

# Meat quality and thermotolerance in *Bos Indicus* influenced cattle

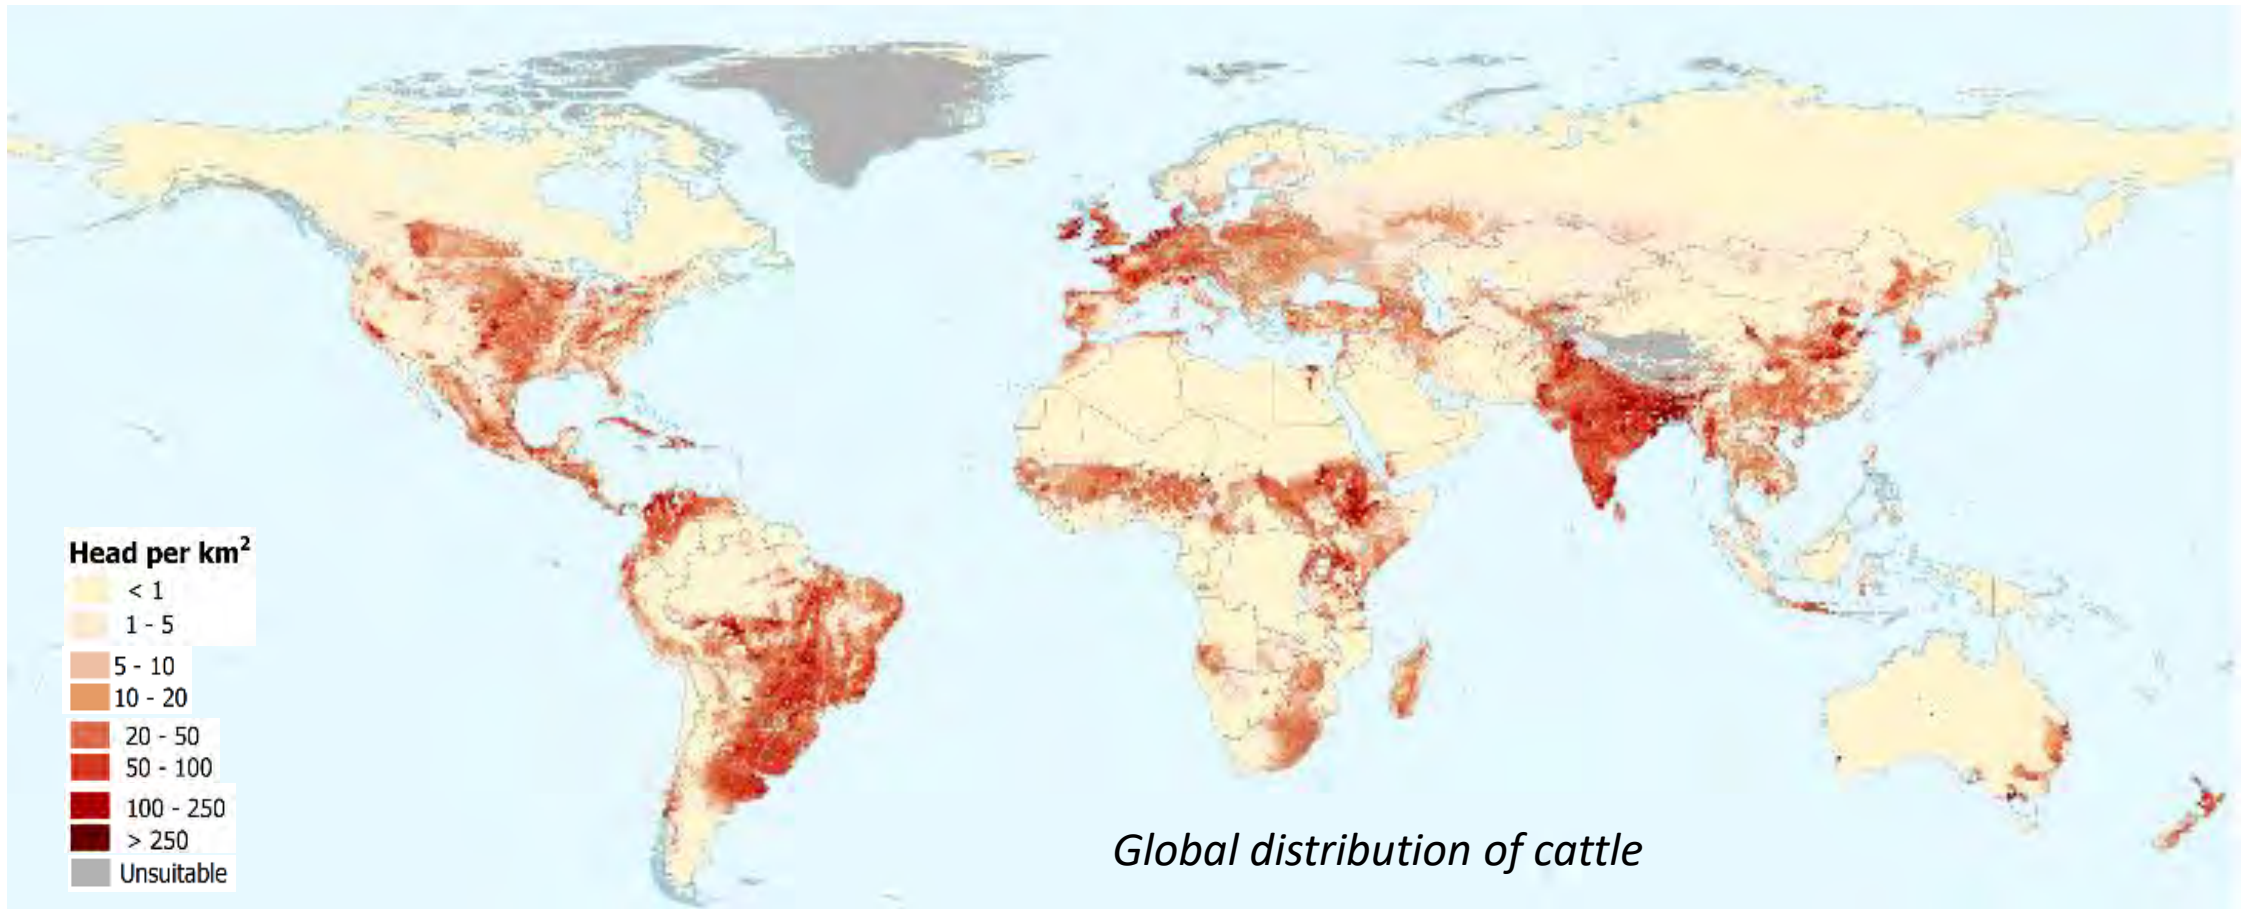

Raluca Mateescu | Associate Professor  
Animal Genomics

Department of  
Animal Sciences

**UF** | UNIVERSITY of  
**FLORIDA**

# Beef cattle in the world

- > **50%** cattle in the world – maintained in hot and humid environments
  - including ~ 40% of beef cows in US

# *Bos Indicus* cattle

- Approximately **80%** of global beef production is *Bos Indicus* based.

## *Bos indicus* germplasm:

- Critical role in US and worldwide beef production
- Particularly when used as part of a well-structured crossbreeding program

- **Adapted to heat and humidity**
- **Resistant (or at least tolerant) to internal and external parasites**
- **In crossbreeding systems produce improved cattle:**
  - Fertile
  - Gain well
  - Long lived

# Two areas of interest

## Meat Quality

- Top priority for beef industry
  - Great power to influence demand
  - Can be improved
- V. important for *B. indicus* crosses
  - Routinely penalized for relatively low marbling score.
  - Routinely penalized for perceived inadequate tenderness

## Thermotolerance

- Climatic stress - major limiting factor of production efficiency
- Genomic tools can help select
  - Animals with superior ability for both thermal adaptation and food production
  - Energy-efficient, sustainable approach to meet the challenge of global climate change.

A decorative border consisting of a continuous DNA double helix structure, with red and blue strands, framing the central text area.

## SNP – genetic marker

UF Brahman, n = 241

# Combination of markers in calpastatin

A decorative border consisting of a continuous DNA double helix structure, with red and blue strands, runs along the top, bottom, and left edges of the slide.

# Thermo- tolerance

# In response to heat stress, cattle will regulate:

## Heat Production

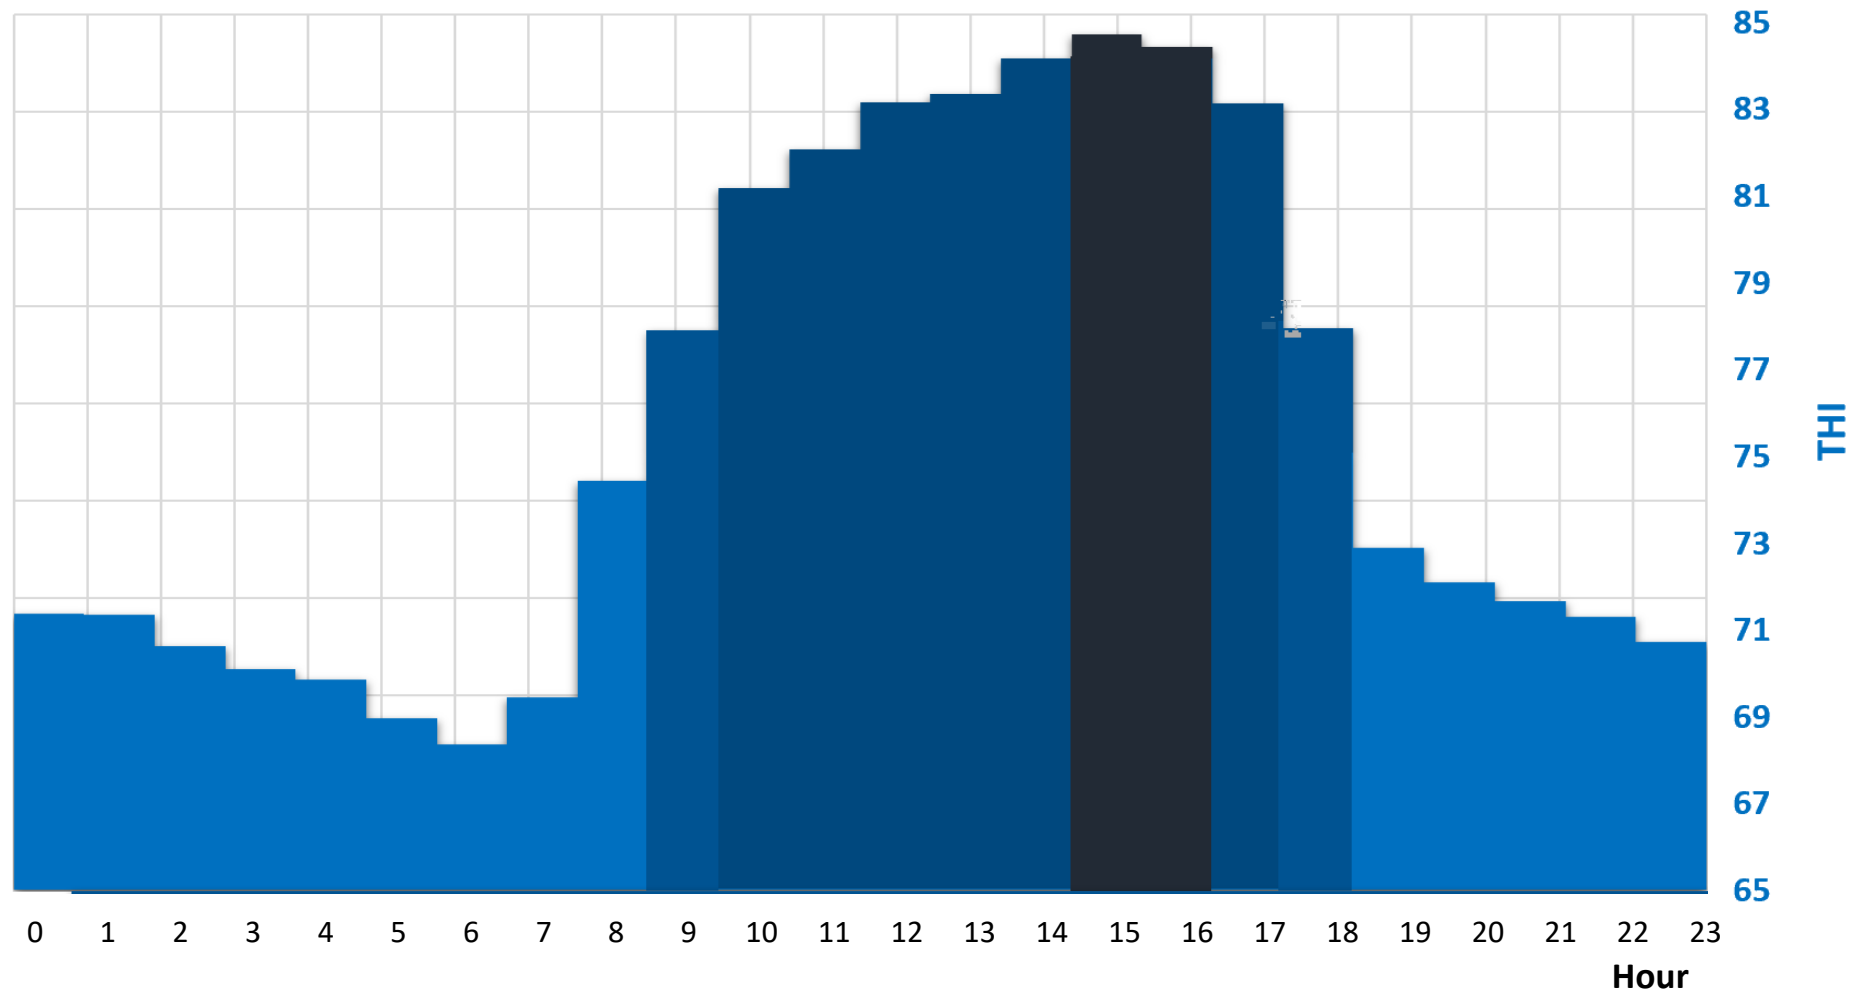

- Modulating basal metabolic rate
- Changing: feed intake, growth, lactation, activity

## Heat Exchange

- Blood flow to the skin
- Evaporative heat loss through sweating & panting

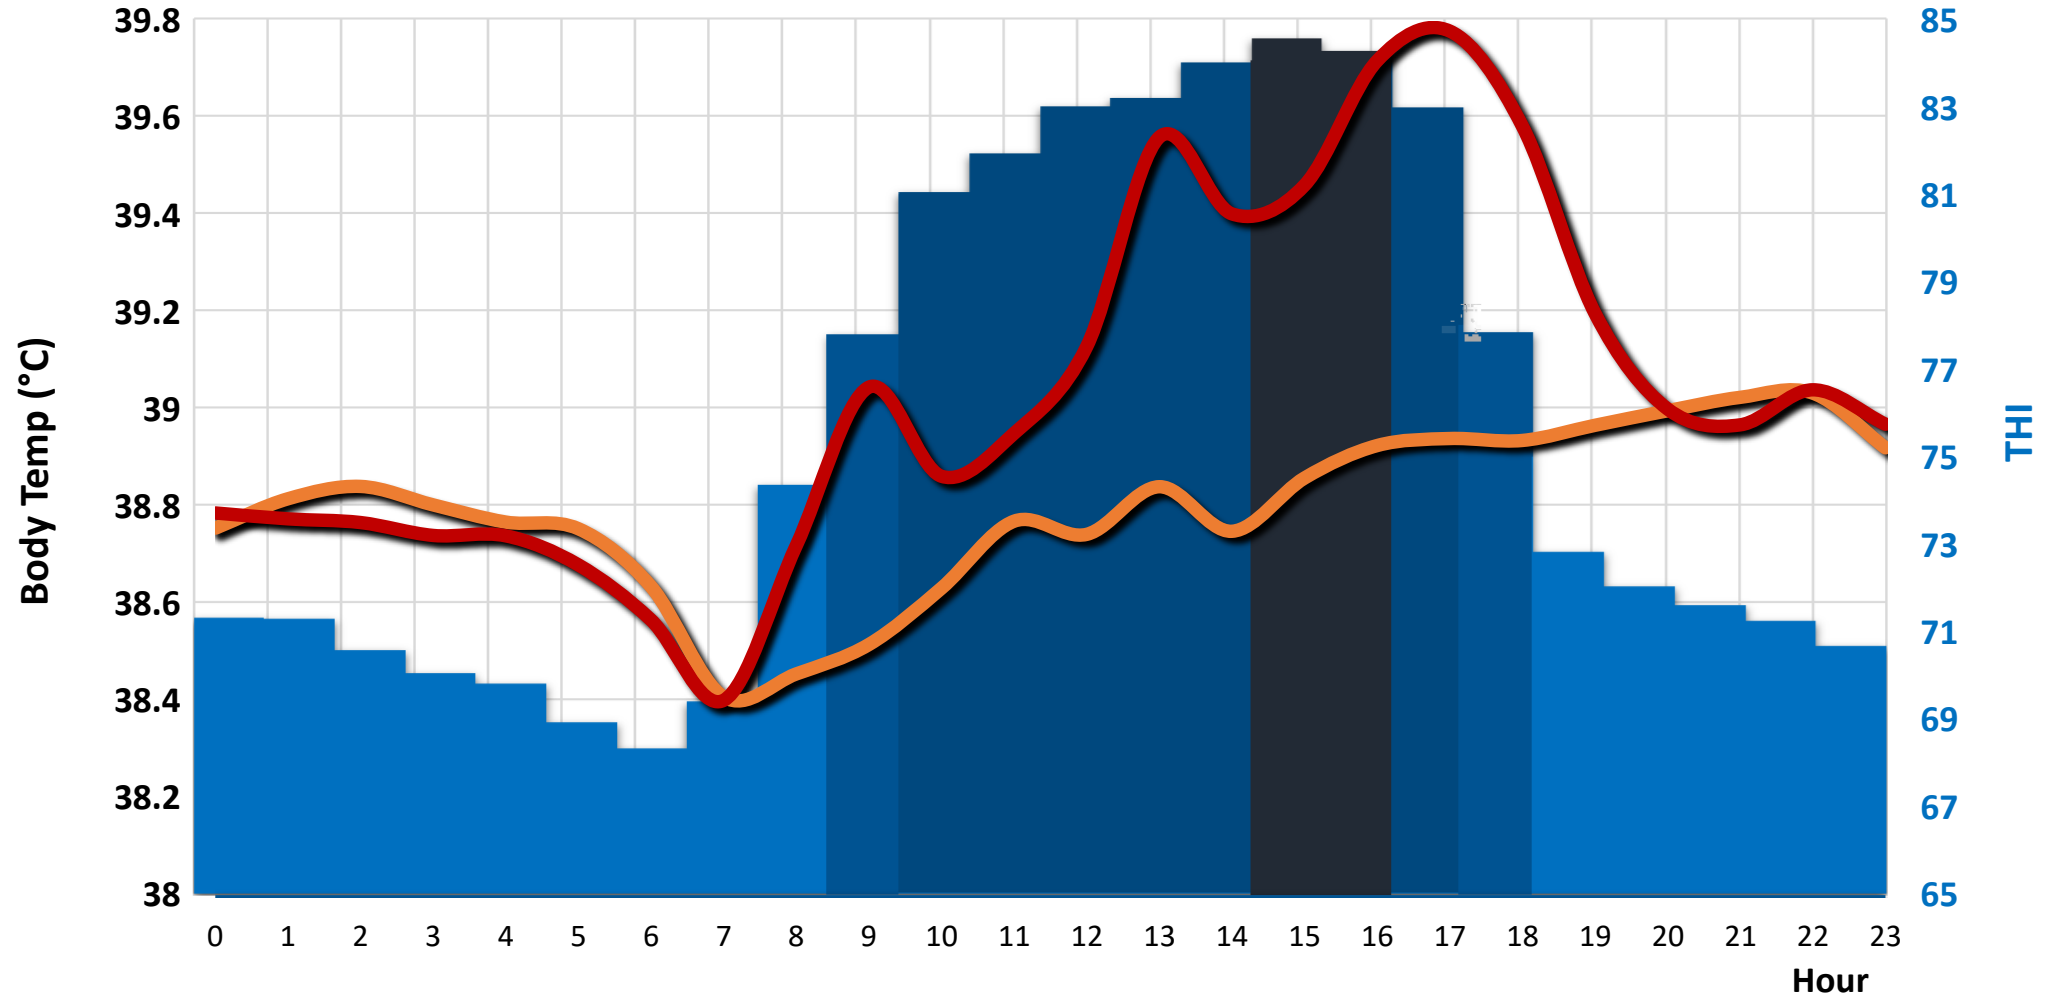

**Goal:** Develop genomic tools to select for superior ability for both thermal adaptation and food production.

# Breed effect on body temperature

- $\geq 84$  Critical heat stress
- 79 - 83 Major heat stress
- 75 - 78 Moderate heat stress
- $\leq 75$  Minimal heat stress

# Take-home points

## Meat Quality

- The USDA grading system (marbling and maturity) - limited in predicting eating quality (**tenderness**).
- Existing genomic tests, developed mostly on *Bos Taurus* data, are not predictive in our **Brahman** influenced cattle populations.

## Thermotolerance

- Selection for production ignoring **adaptability** = animals more sensitive to heat stress
- Variation in **coat** and **skin** properties = allows selection for increased thermotolerance without affecting production.

# Thermotolerance measurements

- 
- Vaginal **temperature** 15 min over 5 days
  - Environmental data: temperature, humidity, **THI**
  - **Sweating** rate
  - **Coat**: color, coat score, hair length & diameter
  - **Temperament**: chute and exit score
  - Body **condition** score
  - **Skin** biopsies: for histology & gene expression
  - **Weight gain** over the summer/fall
  - Rump fat and rib fat ultrasound
  - Subsequent **pregnancy** status
  - **250K** genotypes

# Conclusion and future work

- Critical to identify genes and gene **pathways** for thermotolerance independent of production traits.
- Ultimate goal: cattle with high productivity and resistant to heat stress
  - Genomic **selection** within indicine-influenced breeds.
  - **Gene editing** for rapid incorporation into non-adapted breeds.
- Approach: **GWAS** for all traits (gene networks) combined with **gene expression**.

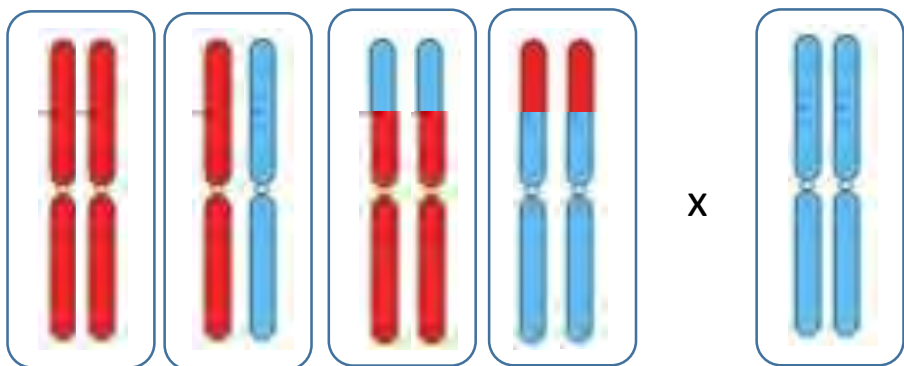

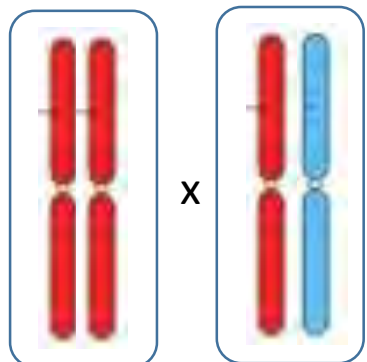

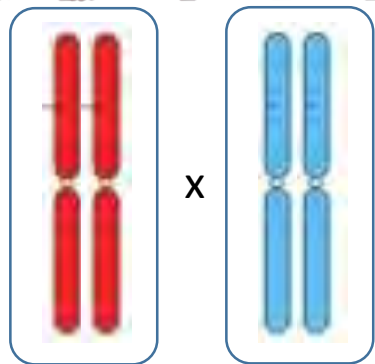

# Conclusion and future work

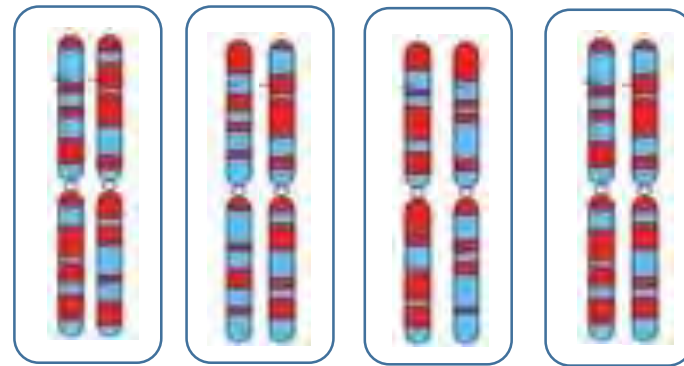

- **Reaction norm** – good approach to describe **phenotypic plasticity** of core body temperature in response to environmental heat stress.
- Cattle with different **Brahman** percentage vary in their phenotypic plasticity.
- The **phenotypic plasticity** has a genetic component ( $h^2 \sim .24$ )

Programs to utilize the genetic component to improve **phenotypic plasticity** can be implemented.

.....

# Take-home points

- **Brahman** cattle – critical role in US and worldwide beef production.
- Genetics of **thermotolerance** – will allow for improved adaptability in Brahman crosses.
- **Meat quality** – great improvements in tenderness
- Need **breed specific genomic** tool for accurate prediction.

# Breed-specific genomic tools

- To meet consumer expectation, the average **tenderness** needs to be **improved** and the **variation** in meat tenderness must be **controlled/managed**
- To be effective - genomic tools need to be developed in the **target** populations

Large resource populations with phenotypes are required for discovery and estimation.

# Thermotolerance

- **Heat stress** - negative impact on US and global livestock productivity.
- > **50%** cattle in the world – maintained in hot and humid environments
- When cattle experience heat stress:

Feed intake  
Milk production  
Growth  
Reproduction
