## ANIMAL BREEDING NOTES

## CHAPTER 3

## EIGENVALUES, EIGENVECTORS, AND DIAGONALIZATION OF A SQUARE

 MATRIX
## Eigenvalues and eigenvectors

The eigenvalues of a square matrix $\mathrm{A}_{\mathrm{n} \times \mathrm{n}}$ are the n roots of its characteristic polynomial:

$$
|A-\lambda I|=0
$$

The set of eigenvalues (or latent roots) is called the spectrum and can be denoted as:

$$
\lambda(\mathrm{A})=\left\{\lambda_{1}, \lambda_{2}, \ldots, \lambda_{\mathrm{n}}\right\}
$$

Associated with these n eigenvalues are n eigenvectors. The eigenvectors must satisfy the equation:

$$
A u_{i}=\lambda_{i} u_{i}, i=1, \ldots, n
$$

where $u_{i}=i^{\text {th }}$ eigenvector.
Diagonalizable matrix: a square matrix A is called diagonalizable if there is an invertible matrix P such that $\mathrm{P}^{-1} \mathrm{AP}$ is diagonal. The matrix P is said to diagonalize A (Anton, 1981, pg. 269).

Theorem: If A is an $\mathrm{n} \times \mathrm{n}$ matrix the following statements are equivalent:
(a) A is diagonalizable, and
(b) A has n linearly independent eigenvectors.

Proof:
(a) $\Rightarrow$ (b) Assume A is diagonalizable, then there is an invertible matrix $P$ such that:

$$
\begin{aligned}
\mathrm{P}^{-1} \mathrm{AP} & =\mathrm{D} \\
\mathrm{AP} & =\mathrm{PD}
\end{aligned}
$$

$$
\left[\begin{array}{llll}
\mathrm{Ap}_{1} & \mathrm{Ap} & \ldots & A p_{n}
\end{array}\right]=\left[\begin{array}{lllll}
\lambda_{1} p_{1} & \lambda_{2} \mathrm{p}_{2} & \ldots & \lambda_{\mathrm{n}} \mathrm{p}_{\mathrm{n}}
\end{array}\right]
$$

$$
\Rightarrow A p_{i}=\lambda_{i} p_{i}, \quad i=1, \ldots, n
$$

where
$\left\{\lambda_{i}\right\} \quad$ are the eigenvalues of $A$, and
$\left\{p_{i}\right\} \quad$ are the corresponding eigenvectors, which are independent because $\mathrm{P}^{-1}$ exists.
(b) $\Rightarrow$ (a) Assume A has n linearly independent eigenvectors $\left(\mathrm{p}_{\mathrm{i}}\right)$ with associated eigenvalues $\left\{\lambda_{i}\right\}$. Consider the product,

$$
\mathrm{A}\left[\mathrm{p}_{1} \mathrm{p}_{2} \ldots \mathrm{p}_{\mathrm{n}}\right]
$$

But $\mathrm{Ap}_{\mathrm{i}}=\lambda_{\mathrm{i}} \mathrm{p}_{\mathrm{i}}, \quad \mathrm{i}=1, \ldots, \mathrm{n}$. Thus, $\mathrm{AP}=\mathrm{PD}$, where $\mathrm{D}=\operatorname{diag}\left\{\lambda_{\mathrm{i}}\right\}$.
Since the columns of P are linearly independent, $\mathrm{P}^{-1}$ exists, so

$$
\mathrm{P}^{-1} \mathrm{AP}=\mathrm{D} \Rightarrow \mathrm{~A} \text { is diagonalizable. }
$$

This theorem indicates that if a square matrix A is diagonalizable, we can find a set of n linearly independent eigenvectors. The matrix A can be singular or non-singular.

Placing the latent vectors of matrix A together to form a matrix we obtain:

$$
\mathrm{U}=\left[\mathrm{u}_{1} \mathbf{u}_{2} \ldots \mathrm{u}_{\mathrm{n}}\right]
$$

where $U$ is an $n \times n$ square matrix, $\operatorname{rank}(U)=n$, hence $U$ is non-singular and $U^{-1}$ exists. Thus, forming the equations $A u_{i}=\lambda u_{i}$, for $i=1, \ldots$, $n$ we get:

$$
\mathrm{A}\left[\mathbf{u}_{1} \mathbf{u}_{2} \ldots \mathbf{u}_{\mathrm{n}}\right]=\left[\mathbf{u}_{1} \mathbf{u}_{2} \ldots \mathbf{u}_{\mathrm{n}}\right] \operatorname{diag}\left\{\lambda_{\mathrm{i}}\right\}
$$

or

$$
\begin{aligned}
& \mathrm{AU}=\mathrm{UD} \\
& \Rightarrow \quad \mathrm{~A}=\mathrm{UDU}^{-1} \text { and } \quad \mathrm{D}=\mathrm{U}^{-1} \mathrm{AU}
\end{aligned}
$$

where

$$
\mathrm{D}=\text { canonical form of } \mathrm{A} \text { under similarity. }
$$

Furthermore, if $\mathbf{A}$ is symmetric, i.e., $\mathrm{A}^{\prime}=\mathrm{A}$, there exist an orthogonal $\mathbf{U}$ (i.e., $\mathrm{UU}^{\prime}=\mathrm{U}^{\prime} \mathrm{U}=\mathrm{I}$ )
such that
$\mathrm{A}=\mathrm{UDU}^{\prime}$
and
$\mathrm{D}=\mathrm{U}^{\prime} \mathrm{AU}$

## Spectral Decomposition

For a non-symmetric matrix $A_{n \times n}$, the spectral decomposition is:

$$
\mathrm{A}=\lambda_{1} \mathrm{u}_{1} \mathrm{v}^{1}+\lambda_{2} \mathrm{u}_{2} \mathrm{v}^{2}+\cdots+\lambda_{\mathrm{n}} \mathrm{u}_{\mathrm{n}} \mathrm{v}^{\mathrm{n}}
$$

where $\left\{\lambda_{i}\right\}=$ eigenvalues of A
$\left\{u_{i}\right\}=$ eigenvectors of A
$\left\{\mathrm{v}^{\mathrm{i}}\right\}=$ rows of the matrix $\mathrm{U}^{-1}$
Proof:

$$
\mathrm{A}=\mathrm{UDU}^{-1}
$$

Let $\left[\begin{array}{r}\mathrm{v}_{1} \\ \mathrm{v}_{2} \\ \vdots \\ \mathrm{v}_{\mathrm{n}}\end{array}\right]$ be the row vectors of matrix $\mathrm{U}^{-1}$.

Then, $A=\left[\begin{array}{llll}u_{1} & u_{2} & \cdots & u_{n}\end{array}\right]\left[\begin{array}{llll}\lambda_{1} & & & \\ & \lambda_{2} & & \\ & & \ddots & \\ & & & \lambda_{n}\end{array}\right]\left[\begin{array}{c}\mathrm{v}^{1} \\ \mathrm{v}^{2} \\ \vdots \\ \mathrm{v}^{\mathrm{n}}\end{array}\right]$

$$
\mathrm{A}=\lambda_{1} \mathrm{u}_{1} \mathrm{v}^{1}+\lambda_{2} \mathrm{u}_{2} \mathrm{v}^{2}+\cdots+\lambda_{\mathrm{n}} \mathrm{u}_{\mathrm{n}} \mathrm{v}^{\mathrm{n}}
$$

For a symmetric matrix $A_{n \times n}$, the spectral decomposition is:

$$
\mathrm{A}=\lambda_{1} \mathrm{u}_{1} \mathrm{u}^{1 \prime}+\lambda_{2} \mathrm{u}_{2} \mathrm{u}^{2 \prime}+\cdots+\lambda_{\mathrm{n}} \mathrm{u}_{\mathrm{n}} \mathrm{u}^{\mathrm{n} \prime}
$$

where $\left\{\mathrm{u}^{\mathrm{i}}\right\}=$ rows of the symmetric matrix $\mathrm{U}^{-1}$.
Thus, if the set of linearly independent eigenvectors $\left\{u_{i}\right\}$ of a non-singular matrix $A$ is orthogonalized, the spectral decomposition of A becomes:

$$
\mathrm{A}=\lambda_{1} \mathrm{u}_{1} \mathrm{u}^{1 \prime}+\lambda_{2} \mathrm{u}_{2} \mathrm{u}^{2 \prime}+\cdots+\lambda_{\mathrm{n}} \mathrm{u}_{\mathrm{n}} \mathrm{u}^{\mathrm{n} \prime}
$$

where $\left\{u_{i}\right\}=$ orthogonal eigenvectors of $A\left(u_{i}^{\prime} u_{i^{\prime}}\right)=0$.
Furthermore, if the $\left\{u_{i}\right\}$ are normalized such that $u_{i}{ }^{\prime} u_{i}=1$, the spectral decomposition is:

$$
\mathrm{A}=\lambda_{1} \mathrm{e}_{1} \mathrm{e}_{1}^{\prime}+\lambda_{2} \mathrm{e}_{2} \mathrm{e}_{2}^{\prime}+\cdots+\lambda_{\mathrm{n}} \mathrm{e}_{\mathrm{n}} \mathrm{e}_{\mathrm{n}}^{\prime}
$$

where $\left\{\mathrm{e}_{\mathrm{i}}\right\}=$ orthonormal eigenvectors of $\mathrm{A}\left(\mathrm{e}_{\mathrm{i}^{\prime}} \mathrm{e}_{\mathrm{i}^{\prime}}=0\right.$ and $\left.\mathrm{e}_{\mathrm{i}}{ }^{\prime} \mathrm{e}_{\mathrm{i}}=1\right)$.

## Results:

1) If $A$ is an $n \times n$ matrix, $U$ is an $n \times n$ non-singular matrix and $D=P A P^{-1}$, then the characteristic polynomial, characteristic roots, trace, determinant and rank of D are identical to those of A.

Proof:
(a) $|\mathrm{D}-\lambda \mathrm{I}|=\left|\mathrm{PAP}^{-1}-\lambda \mathrm{I}\right|$

$$
\begin{aligned}
& =\left|\mathrm{PAP}^{-1}-\lambda \mathrm{PP}^{-1}\right| \\
& =\left|\mathrm{P}(\mathrm{~A}-\lambda \mathrm{I}) \mathrm{P}^{-1}\right| \\
& =|\mathrm{P}||\mathrm{A}-\lambda \mathrm{I}|\left|\mathrm{P}^{-1}\right| \\
& =|\mathrm{A}-\lambda \mathrm{I}|\left|\mathrm{PP}^{-1}\right| \\
& =|\mathrm{A}-\lambda \mathrm{I}||\mathrm{I}| \\
& =|\mathrm{A}-\lambda \mathrm{I}|
\end{aligned}
$$

$\Rightarrow$ the characteristic polynomial and the characteristic roots of D and A are the same.
(b) trace $(\mathrm{D})=\operatorname{trace}\left(\mathrm{PAP}^{-1}\right)$

$$
\begin{aligned}
& =\operatorname{trace}\left(\mathrm{P}^{-1} \mathrm{PA}\right) \\
& =\operatorname{trace}(\mathrm{A})
\end{aligned}
$$

Also, note that

$$
\operatorname{trace}(\mathrm{D})=\sum_{i=1}^{n} \lambda_{i}=\operatorname{trace}(\mathrm{A})
$$

(c) $|\mathrm{D}|=\left|\mathrm{PAP}^{-1}\right|$

$$
\begin{aligned}
& =|\mathrm{P}||\mathrm{A}|\left|\mathrm{P}^{-1}\right| \\
& =|\mathrm{P}|\left|\mathrm{P}^{-1}\right||\mathrm{A}|
\end{aligned}
$$

But the product of the determinants of two square matrices of the same order is equal to the determinant of the product of these matrices (Searle, 1966, pg. 76), thus

$$
\begin{aligned}
|\mathrm{D}| & =\left|\mathrm{PP}^{-1}\right||\mathrm{A}| \\
|\mathrm{D}| & =|\mathrm{A}|
\end{aligned}
$$

where

$$
|\mathrm{D}|=\prod_{i_{-} 1}^{n} \lambda_{i}=|\mathrm{A}|
$$

(d) $\operatorname{rank}(\mathrm{D})=\operatorname{rank}\left(\mathrm{PAP}^{-1}\right)$

```
rank (PA) \leq rank (A)
```

Let $\mathrm{B}=\mathrm{PA} \Rightarrow \mathrm{A}=\mathrm{P}^{-1} \mathrm{~B}$.

$$
\begin{aligned}
\operatorname{rank}\left(\mathrm{A}=\mathrm{P}^{-1} \mathrm{~B}\right) & \leq \operatorname{rank}(\mathrm{B}) \quad=\operatorname{rank}(\mathrm{PA}) \\
\Rightarrow \quad \operatorname{rank}(\mathrm{PA}) & =\operatorname{rank}(\mathrm{A})
\end{aligned}
$$

Similarly,

$$
\operatorname{rank}\left(\mathrm{BP}^{-1}\right) \leq \operatorname{rank}(\mathrm{B})
$$

Let $\mathrm{C}=\mathrm{BP}^{-1} \Rightarrow \mathrm{~B}=\mathrm{CP}$.

$$
\begin{aligned}
\operatorname{rank}(\mathrm{B}=\mathrm{CP}) & \leq \operatorname{rank}(\mathrm{C}) \quad=\operatorname{rank}\left(\mathrm{BP}^{-1}\right) \\
\Rightarrow \quad \operatorname{rank}\left(\mathrm{BP}^{-1}\right) & =\operatorname{rank}(\mathrm{B})
\end{aligned}
$$

Thus,

$$
\begin{aligned}
\operatorname{rank}\left(\mathrm{PAP}^{-1}\right) & =\operatorname{rank}\left(\mathrm{BP}^{-1}\right) \\
& =\operatorname{rank}(\mathrm{B}) \\
& =\operatorname{rank}(\mathrm{PA}) \\
& =\operatorname{rank}(\mathrm{A}) \\
\Rightarrow \quad \operatorname{rank}(\mathrm{D})= & \operatorname{rank}\left(\mathrm{PAP}^{-1}\right)=\operatorname{rank}(\mathrm{A})
\end{aligned}
$$

(Proof taken from Goldberger, 1964, pg. 25 \& 29)
2) If D is a diagonal matrix its latent roots are its diagonal elements.

Proof:

$$
|D-\lambda I|=0
$$

$$
\begin{aligned}
\left|\left\{\mathrm{d}_{\mathrm{ii}}-\lambda\right\}\right| & =0 \\
\left|\left\{\mathrm{~d}_{\mathrm{ii}}-\lambda\right\}\right| & =\left(\mathrm{d}_{11}-\lambda\right)\left(\mathrm{d}_{22}-\lambda\right) \cdots\left(\mathrm{d}_{\mathrm{nn}}-\lambda\right) \\
\Rightarrow \quad\left\{\lambda_{\mathrm{i}}\right. & \left.=\mathrm{d}_{\mathrm{ii}}\right\}
\end{aligned}
$$

3) For a symmetric matrix $A$, if

$$
\left(A-\lambda_{1} I\right) u_{1}=0 \quad \text { and } \quad\left(A-\lambda_{2} I\right) u_{2}=0
$$

where

$$
\lambda_{1} \neq 0, \lambda_{2} \neq 0 \text { and } \lambda_{1} \neq \lambda_{2}
$$

then

$$
\mathrm{u}_{1}{ }^{\prime} \mathbf{u}_{2}=0 .
$$

Proof:

$$
\begin{aligned}
& \mathrm{u}_{2}{ }^{\prime}\left(\mathrm{A}-\lambda_{1} \mathrm{I}\right) \mathrm{u}_{1} \\
& =\mathrm{u}_{2}{ }^{\prime} A \mathrm{u}_{1}-\lambda_{1} \mathrm{u}_{2}{ }^{\prime} \mathrm{u}_{1} \\
& =0 \\
\Rightarrow \quad \lambda_{1} \mathrm{u}_{2}^{\prime} \mathrm{u}_{1} & =\mathrm{u}_{2}{ }^{\prime} A u_{1}
\end{aligned}
$$

Similarly,

$$
\lambda_{2} \mathrm{u}_{1}{ }^{\prime} \mathrm{u}_{2}=\mathrm{u}_{1}{ }^{\prime} \mathrm{Au}_{2}
$$

But

$$
\mathrm{u}_{2}{ }^{\prime} \mathrm{u}_{1} \quad=\mathrm{u}_{1}{ }^{\prime} \mathrm{u}_{2}
$$

and

$$
\begin{aligned}
\mathrm{u}_{2}^{\prime} \mathrm{A} u_{1} & =\left(\mathrm{u}_{2}^{\prime} A u_{1}\right)^{\prime} \\
& =\mathrm{u}_{1}^{\prime} \mathrm{A}^{\prime} \mathrm{u}_{2} \\
& =\mathrm{u}_{1}^{\prime} A \mathrm{u}_{2} \\
\Rightarrow \quad \lambda_{2} \mathrm{u}_{1}^{\prime} \mathrm{u}_{2} & =\lambda_{1} \mathrm{u}_{2}^{\prime} \mathrm{u}_{1}
\end{aligned}
$$

or

$$
\mathrm{u}_{1}{ }^{\prime} \mathrm{u}_{2}=\frac{\lambda_{1}}{\lambda_{2}} \mathrm{u}_{2}{ }^{\prime} \mathrm{u}_{1}
$$

But $\quad \lambda_{1} \neq \lambda_{2} \neq 0$
$\Rightarrow \quad \mathrm{u}_{1}{ }^{\prime} \mathrm{u}_{2}=0$
4) For a symmetric matrix $A$ there is an orthogonal matrix $P$ that diagonalizes $A$. Then, the latent roots of A are the diagonal elements of $\mathrm{D}=\mathrm{P}^{\prime} \mathrm{AP}$ and the rank $(\mathrm{A})=$ number of diagonal elements of D.

Proof:
(a) $|\mathrm{D}-\lambda \mathrm{I}|=\left|\mathrm{P}^{\prime} \mathrm{AP}-\lambda \mathrm{I}\right|$
$=\left|P^{\prime}(\mathrm{A}-\lambda \mathrm{I}) \mathrm{P}\right|$
$=|\mathrm{A}-\lambda \mathrm{I}|\left|\mathrm{P}^{\prime} \mathrm{P}\right|$
$=|\mathrm{A}-\lambda \mathrm{I}|$
b) $\operatorname{rank}(\mathrm{D})=\operatorname{rank}\left(\mathrm{P}^{\prime} \mathrm{AP}\right)$
$=\operatorname{rank}(\mathrm{A})$, by 1$)(\mathrm{d})$ above
$=$ number of diagonal elements of D

## Latent roots all different

If the latent roots of a matrix $\mathrm{A}_{\mathrm{n} \times \mathrm{n}}$ are all different, then the corresponding latent vectors are linearly independent. Furthermore, if the matrix A is symmetric, the latent vectors are mutually orthogonal.

## Multiple latent roots

If various latent roots are the same, then a linearly independent set of vectors should be found for each set of repeated latent roots.

For a symmetric matrix $A_{n \times n}$ with multiple latent roots, a procedure to obtain pairwise orthogonal sets of eigenvectors for each set of repeated latent roots is the following:
(a) Given that the rank $\left(\mathrm{A}-\lambda_{\mathrm{i}} \mathrm{I}\right)=\mathrm{n}-\mathrm{m}_{\mathrm{i}}$, for $\mathrm{i}=1, \ldots$, n , where $\mathrm{m}_{\mathrm{i}}=$ multiplicity of $\lambda_{\mathrm{i}}$ (i.e., the number of time $\lambda_{i}$ appears), the equation

$$
\left(\mathrm{A}-\lambda_{\mathrm{i}} \mathrm{I}\right) \mathrm{u}_{\mathrm{i}}=0
$$

has $\mathrm{m}_{\mathrm{i}}$ linearly independent non-null (LINN) solutions $u_{i}$. Denote one solution by $\mathrm{v}_{\mathrm{il}}$. Now consider solving the system

$$
\begin{aligned}
\left(\mathrm{A}-\lambda_{\mathrm{i}} \mathrm{I}\right) \mathrm{u}_{\mathrm{i}} & =0 \\
\mathrm{v}_{\mathrm{i} 1}{ }^{\prime} \mathrm{u}_{\mathrm{i}} & =0
\end{aligned}
$$

simultaneously for $u_{i}$. This set has $m_{i-1}$ LINN. Any one of them, e.g., $u_{i 2}$ is a latent vector of $A$ and it is orthogonal to $u_{i 1}$ and to any latent vector corresponding to $\lambda_{i^{\prime}} \neq \lambda_{i}$ because of the orthogonality property of latent vectors from different latent roots (see result [3] above).

If $m_{i}=3$, solve for $v_{i 3}$ using the set of equations:

$$
\begin{aligned}
\left(\mathrm{A}-\lambda_{\mathrm{i}} \mathrm{I}\right) \mathrm{u}_{\mathrm{i}} & =0 \\
\mathrm{v}_{\mathrm{i} 1}{ }^{\prime} \mathrm{u}_{\mathrm{i}} & =0 \\
\mathrm{v}_{\mathrm{i} 2}{ }^{\prime} \mathrm{u}_{\mathrm{i}} & =0
\end{aligned}
$$

This equation system yields $m_{i-2}$ LINN solutions for $u_{i}$.
(b) Continue this process until all the $m$ solutions are obtained. The set of eigenvalues, $\left\{u_{i}\right\}$, obtained this way are pairwise orthogonal within and across sets of repeated eigenvalues. The
matrix formed by these eigenvectors, however, is not orthogonal, i.e., $U^{\prime} \neq U^{\prime} U \neq I$. To orthogonalize the matrix $U$, simply divide each eigenvector by its length, i.e., by $\left[\mathrm{u}_{\mathrm{i}}{ }^{\prime} \mathrm{u}_{\mathrm{i}}\right]^{1 / 2}$. The resulting matrix is orthogonal because $\mathrm{UU}^{\prime}=\mathrm{I} \Rightarrow \mathrm{U}^{\prime} \mathrm{U}=\mathrm{I}$.

For a non-symmetric matrix A there is no guarantee that the set of linearly independent eigenvectors $\left\{u_{i}\right\}$ will be pairwise orthogonal, i.e., $u_{i}{ }^{\prime} u_{i}$ may not be zero for some pairs of vectors. Hence, to orthogonalize a matrix of eigenvectors $U$ for non-symmetric matrix $A$ use the Gram-Schmidt process or other suitable orthogonalization procedure (e.g., see Golub and Van Loan, 1983).

## Gram-Schmidt process

Given a linearly independent set of vectors $\left\{\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{n}}\right\}$ (i.e., an arbitrary basis), there exists a set of mutually perpendicular (i.e., orthogonal) vectors $\left\{\mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{n}}\right\}$ that have the same linear span.

To construct a mutually orthogonal set of vectors $\left\{u_{i}\right\}$ from the set of vectors $\left(x_{i}\right\}$ proceed as follows (for proof see Scheffé, 1959, pg. 382).
(a) $\operatorname{Set} u_{1}=x_{1}$.
(b) Compute vectors $u_{2}$ to $u_{n}$ using the formula:

$$
\mathrm{u}_{\mathrm{i}}=\mathrm{x}_{\mathrm{i}}-\sum_{\mathrm{j}=1}^{\mathrm{i}-1} \frac{\left(\mathrm{x}_{\mathrm{i}}{ }^{\prime} \mathrm{u}_{\mathrm{j}}\right)}{\mathrm{u}_{\mathrm{j}}^{\prime} \mathrm{u}_{\mathrm{j}}} \mathrm{u}_{\mathrm{j}}, \quad 2 \leq \mathrm{j} \leq \mathrm{n}
$$

For example:

$$
\mathrm{u}_{2}=\mathrm{x}_{2}-\frac{\left(\mathrm{x}_{2}^{\prime} \mathrm{u}_{1}\right)}{\mathrm{u}_{1}^{\prime} \mathrm{u}_{1}} \mathrm{u}_{1}
$$

$$
\begin{equation*}
u_{3}=x_{3}-\frac{\left(\mathrm{x}_{3}^{\prime} \mathrm{u}_{1}\right)}{\mathrm{u}_{1}^{\prime} \mathrm{u}_{1}} \mathrm{u}_{1}-\frac{\left(\mathrm{x}_{3}{ }^{\prime} \mathrm{u}_{2}\right)}{\mathrm{u}_{2}^{\prime} \mathrm{u}_{2}} \mathrm{u}_{2} \tag{3-11}
\end{equation*}
$$

We can also build a mutually orthogonal set of vectors $\left\{z_{i}\right\}$ from the set $\left\{x_{i}\right\}$ which, in addition, have length equal to 1 . This process, called normalizing a set of vectors, can be easily accomplished by dividing each vector $u_{i}$ by its length, i.e.,

$$
Z_{i}=\frac{u_{i}}{\left[u_{i}{ }^{\prime} u_{i}\right]^{1 / 2}} \text { for } i=1, \ldots, n
$$

where $\left[u_{i}\right]^{1 / 2}$ is the length of vector $u_{i}$.

## Remarks:

(1) $\left[z_{i}{ }^{\prime} z_{i}\right]=\frac{\left[\mathrm{u}_{\mathrm{i}}{ }^{\prime} \mathrm{u}_{\mathrm{i}}\right]^{\prime / 2}}{\left[\mathrm{u}_{\mathrm{i}}{ }^{\prime} \mathrm{u}_{\mathrm{i}}\right]^{{ }^{\prime 2}}}=1$
(2) $\left(x z_{j}\right) z_{j}$ is the projection of $x_{i}$ on $z_{j}$.
(3) $\sum_{j=1}^{i-1}\left(\mathrm{xz}_{\mathrm{j}}\right) \mathrm{z}_{\mathrm{j}}$ is the projection of $\mathrm{x}_{\mathrm{i}}$ on the linear span of $\mathrm{z}_{1}, \mathrm{z}_{2}, \ldots, \mathrm{z}_{\mathrm{i}-1}$ (or the span of $\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots$, $\mathrm{X}_{\mathrm{i}-1}$ because both $\left\{\mathrm{z}_{\mathrm{i}}\right\}$ and $\left\{\mathrm{X}_{\mathrm{i}}\right\}$ have the same span).
(4) The Gram-Schmidt (GS) procedure has poor numerical properties. There is typically a severe loss of orthogonality among the computed $\mathrm{z}_{\mathrm{i}}$ (Golub and Van Loan, 1983, pg. 151).

Better methods are:
(a) Modified Gram-Schmidt (Golub \& Van Loan, 1983, pg. 152).
(b) Householder Orthogonalization (Golub \& Van Loan, 1983, pg. 148).

## Computation of eigenvalues and eigenvectors

Consider a matrix $\mathrm{A}_{3 \times 3}$,

$$
A=\left[\begin{array}{ccc}
13 & -4 & 2 \\
-4 & 13 & -2 \\
2 & -2 & 10
\end{array}\right]
$$

## a) Eigenvalues

The characteristic equations of A is:

$$
\left|\begin{array}{rrr}
13-\lambda & -4 & 2 \\
-4 & 13-\lambda & -2 \\
2 & -2 & 10-\lambda
\end{array}\right|=0
$$

To find the latent roots we need to expand the above determinant. The diagonal expansion (appropriate for (A + D) matrices, $\mathrm{D}=$ diagonal, Searle, 1966, pg. 71-73), when the diagonal elements of D are equal, i.e., $\left\{\mathrm{d}_{\mathrm{ii}}\right\}=\{-\lambda\}$. Then, $(-\lambda)^{n}+(-\lambda)^{n-1}\left(a_{11}+a_{22}+\ldots+a_{n n}\right)+(-\lambda)^{n-2}\left\{\left|\begin{array}{ll}a_{11} & a_{12} \\ a_{21} & a_{22}\end{array}\right|+\ldots+\left|\begin{array}{ll}a_{11} & a_{1 n} \\ a_{n 1} & a_{n n}\end{array}\right|\right\}+\ldots+|A|=0$
or

$$
|\mathrm{A}-\lambda \mathrm{I}|=\sum_{\mathrm{i}=0}^{\mathrm{n}}(-\lambda)^{\mathrm{n}-\mathrm{i}} \operatorname{trace}_{\mathrm{i}}(\mathrm{~A})=0
$$

where
$\operatorname{trace}_{0}(\mathrm{~A})=1$
trace $_{i}(\mathrm{~A}) \quad=$ sum of the principal minors (i.e., minors with diagonals that coincide with the diagonal of $|A|$ ) of order $i$ of $|A|$
$\operatorname{trace}_{\mathrm{n}}(\mathrm{A})=|\mathrm{A}|$
Thus, the diagonal expansion for $\mathrm{A}_{3 \times 3}$ above is:

$$
\begin{align*}
&-\lambda^{3}+\lambda^{2}(13+13+10)-\lambda\left\{\left\{\begin{array}{cc}
13 & -4 \\
-4 & 13
\end{array}\left|+\left|\begin{array}{cc}
13 & 2 \\
2 & 10
\end{array}\right|+\left|\begin{array}{cc}
13 & -2 \\
-2 & 10
\end{array}\right|\right\}+\left|\begin{array}{ccc}
13 & -4 & 2 \\
-4 & 13 & -2 \\
2 & -2 & 10
\end{array}\right|=0\right.\right.  \tag{3-13}\\
&-\lambda^{3}+36 \lambda^{2}-\lambda(153+126+126)+1458=0 \\
&-\lambda^{3}+36 \lambda^{2}-405 \lambda+1458=0 \\
& \lambda^{3}-36 \lambda^{2}+405 \lambda-1458=0
\end{align*}
$$

To solve for this third degree polynomial equation:
(1) Find an integer number $\lambda_{1}$ such that:
(a) Is an exact division of the constant 1458
(b) It satisfies the equation $\lambda^{3}-36 \lambda^{2}+405 \lambda-1458=0$
(2) Divide $\lambda^{3}-36 \lambda+405 \lambda-1458$ by $\lambda-\lambda_{1}$. The result of this division is a second degree polynomial, which can be solved by the quadratic formula. The quadratic formula is:

$$
\lambda=\frac{-\mathrm{b} \pm\left[\left(\mathrm{b}^{2}\right)-4(\mathrm{a})(\mathrm{c})\right]^{1 / 2}}{2 \mathrm{a}}
$$

whose solutions satisfy the quadratic equation

$$
\mathrm{a} \lambda^{2}+\mathrm{b} \lambda+\mathrm{c}=0
$$

In our example, the integers $\pm 1, \pm 2, \pm 3, \pm 6$ and $\pm 9$ are exact divisions of 1458 , but only 9 satisfies the above cubic equation, i.e., $(9)^{3}-36(9)^{2}+405(9)-1458=0$. Thus, the first root of the cubic polynomial above is 9 , because this polynomial can be written as:

$$
(\lambda-9)\left(\lambda^{2}+b \lambda+c\right)=0
$$

for some integers $b$ and $c$. To find them, divide the cubic polynomial by $\lambda-9$, i.e.,

$$
\lambda^{3}-36 \lambda^{2}+405 \lambda-1458: \lambda-9=\lambda^{2}-27 \lambda+162
$$

$$
\begin{gathered}
\frac{-\lambda^{3}{ }^{(+)}-9 \lambda^{2}}{0-27 \lambda^{2}+405 \lambda} \\
\frac{e^{(+)} 27 \lambda^{2}(-)}{-^{(-)} 243 \lambda} \\
0+162 \lambda-1458 \\
\Rightarrow \quad \frac{(-) 162 \lambda^{(+)}-1458}{0+0} \\
\Rightarrow \quad(\lambda-9)\left(\lambda^{2}-27 \lambda+162\right)=0 \\
\lambda_{1}=9
\end{gathered}
$$

Solving for the quadratic equation $\lambda^{2}-27 \lambda+162=0$ yields,

$$
\begin{array}{ll}
\Rightarrow & \lambda=\frac{-27 \pm\left[(27)^{2} \pm 4(1)(162)\right]^{1 / 2}}{2(1)} \\
\Rightarrow & \lambda=\frac{27 \pm 9}{2} \\
\Rightarrow & \lambda_{2}=\frac{18}{2}=9
\end{array}
$$

and

$$
\lambda_{3}=\frac{36}{2}=18
$$

which satisfy

$$
(\lambda-9)(\lambda-18)=\lambda^{2}-27 \lambda+162=0
$$

Thus, the set of eigenvalues is:

$$
\left\{\lambda_{1}, \lambda_{2}, \lambda_{3}\right\} \quad=\{9,9,18\}
$$

## b) Eigenvectors

We need to solve the equations:

$$
A u_{i}=\lambda_{i} u_{i}, \text { for } i=1,2,3 .
$$

## Eigenvector for $\boldsymbol{\lambda}_{1}=9$

The set of equations to solve is:

$$
\begin{aligned}
& \left(A-\lambda_{i} I\right) u_{i}=0 \\
& {\left[\begin{array}{rrr}
(13-9) & -4 & 2 \\
-4 & (13-9) & -2 \\
2 & -2 & (10-9)
\end{array}\right]\left[\begin{array}{l}
u_{11} \\
u_{21} \\
u_{31}
\end{array}\right]=0} \\
& {\left[\begin{array}{rrr}
4 & -4 & 2 \\
-4 & 4 & -2 \\
2 & -2 & 1
\end{array}\right]\left[\begin{array}{l}
u_{11} \\
u_{21} \\
u_{31}
\end{array}\right]=0}
\end{aligned}
$$

By theorem 4) of Linear Equations (Chapter 2), a vector of solutions to the above system is given by:

$$
\mathrm{u}_{\mathrm{i}}=(\mathrm{H}-\mathrm{I}) \mathrm{z}
$$

for an arbitrary z , where $\mathrm{H}=\mathrm{GA}$. To obtain G , look for dependencies in A , zero out the dependent rows and columns, and invert the resulting non-singular matrix. The first row of A is equal to ( -1 )row 2 and (2)row 3. The same dependencies exist among columns. Thus,

$$
\mathrm{H}=\mathrm{GA}=\left[\begin{array}{rrr}
1 / 4 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right]\left[\begin{array}{rrr}
4 & -4 & 2 \\
-4 & 4 & -2 \\
2 & -2 & 1
\end{array}\right]=\left[\begin{array}{rrr}
1 & -1 & 1 / 2 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right]
$$

and

$$
\mathrm{u}_{1}=\left[\begin{array}{rrr}
(1-1) & -1 & 1 / 2  \tag{3-16}\\
0 & -1 & 0 \\
0 & 0 & -1
\end{array}\right]\left[\begin{array}{l}
\mathrm{z}_{1} \\
\mathrm{z}_{2} \\
\mathrm{z}_{3}
\end{array}\right]=\left[\begin{array}{r}
-\mathrm{z}_{2}+1 / 2 \mathrm{z}_{3} \\
-\mathrm{z}_{2} \\
-\mathrm{z}_{3}
\end{array}\right]
$$

Arbitrarily choose $z_{2}=-1$ and $z_{3}=0$, then, an eigenvector for $\lambda_{1}=9$ is:

$$
\mathrm{u}_{1}=\left[\begin{array}{l}
1 \\
1 \\
0
\end{array}\right]
$$

Eigenvector for $\lambda_{2}=9$
The system of equations to be solved for $\lambda_{2}=9$ is the same as for $\lambda_{1}=9$. Here we choose a different set of values for $z_{2}$ and $z_{3}$ such that $u_{2}$ and $u_{1}$ are linearly independent, i.e., let

$$
\mathrm{z}_{2}=1 \text { and } \mathrm{z}_{3}=4 .
$$

Thus, the second eigenvector is:

$$
\mathrm{u}_{2}=\left[\begin{array}{r}
1 \\
-1 \\
-4
\end{array}\right]
$$

Note: because A is symmetric, $\mathrm{u}_{2}{ }^{\prime} \mathrm{u}_{1}=0$.
Eigenvector for $\lambda_{3}=18$
The set of equations for $u_{3}$ is:

$$
\left[\begin{array}{rrr}
-5 & -4 & 2 \\
-4 & -5 & -2 \\
2 & -2 & -8
\end{array}\right]\left[\begin{array}{l}
\mathbf{u}_{13} \\
\mathbf{u}_{23} \\
\mathbf{u}_{33}
\end{array}\right]=0
$$

Here, (2) [column 2 - column 1] = column 3. Thus, delete the first row and column, replace them with zeroes and compute G, i.e.,

$$
G=\left[\begin{array}{ccc}
0 & 0 & 0 \\
0 \\
0 & {\left[\begin{array}{cc}
-5 & -2 \\
-2 & -8
\end{array}\right]^{-1}}
\end{array}\right]=\left[\begin{array}{ccc}
0 & 0 & 0 \\
0 & -\frac{2}{9} & \frac{1}{18} \\
0 & \frac{1}{18} & -\frac{5}{36}
\end{array}\right]
$$

Thus, $\mathrm{u}_{3}$ is:

$$
\begin{aligned}
& (\mathrm{GA}-\mathrm{I}) \mathrm{z}=\left\{\begin{array}{|ccc}
0 & 0 & 0 \\
0 & -\frac{2}{9} & \frac{1}{18} \\
0 & \frac{1}{18} & -\frac{5}{36}
\end{array}\left|\left[\begin{array}{rrr}
-5 & -4 & 2 \\
-4 & -5 & -2 \\
2 & -2 & -8
\end{array}\right]-\left[\begin{array}{rrr}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right]\right|\left[\begin{array}{l}
\mathrm{z}_{1} \\
\mathrm{z}_{2} \\
\mathrm{z}_{3}
\end{array}\right]\right. \\
& (\mathrm{GA}-\mathrm{I}) \mathrm{z}=\left[\begin{array}{r}
(0-1) \\
1 \\
1
\end{array}(1-1)\right. \\
& 0 \\
& -\frac{1}{2}
\end{aligned}
$$

Arbitrarily set $\mathrm{z}_{1}=-2$. The resulting eigenvector is:

$$
\mathrm{u}_{3}=\left[\begin{array}{r}
2 \\
-2 \\
1
\end{array}\right]
$$

The matrix U is:

$$
U=\left[\begin{array}{rrr}
1 & 1 & 2  \tag{3-18}\\
1 & -1 & -2 \\
0 & -4 & 1
\end{array}\right]
$$

We can verify that,

$$
\mathrm{D}=\mathrm{U}^{-1} \mathrm{AU}=\left[\begin{array}{rrr}
1 & 1 & 2 \\
1 & -1 & -2 \\
0 & -4 & 1
\end{array}\right]^{-1}\left[\begin{array}{rrr}
13 & -4 & 2 \\
-4 & 13 & -2 \\
2 & -2 & 10
\end{array}\right]\left[\begin{array}{rrr}
1 & 1 & 2 \\
1 & 1 & 2 \\
0 & -4 & 1
\end{array}\right]=\left[\begin{array}{rrr}
9 & 0 & 0 \\
0 & 9 & 0 \\
0 & 0 & 18
\end{array}\right]
$$

and

$$
A=\mathrm{UDU}^{-1}=\left[\begin{array}{rrr}
1 & 1 & 2 \\
1 & -1 & -2 \\
0 & -4 & 1
\end{array}\right]\left[\begin{array}{rrr}
9 & 0 & 0 \\
0 & 9 & 0 \\
0 & 0 & 18
\end{array}\right]\left[\begin{array}{rrr}
1 & 1 & 2 \\
1 & -1 & -2 \\
0 & -4 & 1
\end{array}\right]^{-1}=\left[\begin{array}{rrr}
13 & -4 & 2 \\
-4 & 13 & -2 \\
2 & -2 & 10
\end{array}\right]
$$

## The matrix $D$ is the canonical form of $A$ under similarity

Because A is symmetric in this example, an orthogonal matrix E can be obtained from matrix U by dividing the elements of each vector $u_{i}$ by its length, i.e., by $\left[u_{i}{ }^{\prime} u_{i}\right]^{1 / 2}$.

The lengths of the eigenvectors of A, i.e., the $\left[u_{i}{ }^{\prime} u_{i}\right]^{1 / 2}$ for $i=1,2,3$, are:

$$
\begin{aligned}
& {\left[u_{1}^{\prime} u_{1}\right]^{1 / 2}=\left[(1)^{2}+(1)^{2}+(0)^{2}\right]^{1 / 2}=\sqrt{2}} \\
& {\left[u_{2}^{\prime} u_{2}\right]^{1 / 2}=\left[(1)^{2}+(-1)^{2}+(-4)^{2}\right]^{1 / 2}=\sqrt{18}} \\
& {\left[u_{3}^{\prime} u_{3}\right]^{1 / 2}=\left[(2)^{2}+(-2)^{2}+(1)^{2}\right]^{1 / 2}=3}
\end{aligned}
$$

Thus, the orthogonal matrix of eigenvectors, E , is:

$$
\mathrm{E}=\left[\begin{array}{ccc}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{18}} & \frac{2}{3}  \tag{3-19}\\
\frac{1}{\sqrt{2}} & \frac{-1}{\sqrt{18}} & \frac{-2}{3} \\
0 & \frac{-4}{\sqrt{18}} & \frac{1}{3}
\end{array}\right]
$$

We can verify that $\mathrm{EE}^{\prime}=\mathrm{E}^{\prime} \mathrm{E}=\mathrm{I}$, and

$$
\mathrm{A}=\mathrm{EDE}^{\prime}=\left[\begin{array}{ccc}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{18}} & \frac{2}{3} \\
\frac{1}{\sqrt{2}} & \frac{-1}{\sqrt{18}} & \frac{-2}{3} \\
0 & \frac{-4}{\sqrt{18}} & \frac{1}{3}
\end{array}\right]\left[\begin{array}{ccc}
9 & 0 & 0 \\
0 & 9 & 0 \\
0 & 0 & 18
\end{array}\right]\left[\begin{array}{ccc}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\
\frac{1}{\sqrt{18}} & \frac{-1}{\sqrt{18}} & \frac{-4}{\sqrt{18}} \\
\frac{2}{3} & \frac{-2}{3} & \frac{1}{3}
\end{array}\right]=\left[\begin{array}{ccc}
13 & -4 & 2 \\
-4 & 13 & -2 \\
2 & -2 & 10
\end{array}\right]
$$

and the canonical form of A under orthogonal similarity (only for symmetric A), i.e., D, is:

$$
\mathrm{D}=\mathrm{E}^{\prime} \mathrm{AE}=\left[\begin{array}{ccc}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\
\frac{1}{\sqrt{18}} & \frac{-1}{\sqrt{18}} & \frac{-4}{\sqrt{18}} \\
\frac{2}{3} & \frac{-2}{3} & \frac{1}{3}
\end{array}\right]\left[\begin{array}{rrr}
13 & -4 & 2 \\
-4 & 13 & -2 \\
2 & -2 & 10
\end{array}\right]\left[\begin{array}{ccc}
\frac{1}{2} & \frac{1}{\sqrt{18}} & \frac{2}{3} \\
\frac{1}{\sqrt{2}} & \frac{-1}{\sqrt{18}} & \frac{-2}{3} \\
0 & \frac{-4}{\sqrt{18}} & \frac{1}{3}
\end{array}\right]=\left[\begin{array}{ccc}
9 & 0 & 0 \\
0 & 9 & 0 \\
0 & 0 & 18
\end{array}\right]
$$

Numerical methods to compute eigenvalues and eigenvectors
Eigenvalues: Schur decomposition (Golub and Van Loan, 1983, pg. 192).
Eigenvectors: (Golub and Van Loan, 1983, pg. 238).
Note: To compute eigenvectors when the matrix $[A-\lambda I]$ is full rank:
(a) Substitute zeroes for the elements of the $\mathrm{i}^{\text {th }}$ dependent row and column of matrix A , and compute G,
(b) Compute $u_{i}=[G A-I] z$, and
(c) Assign arbitrary values to the necessary $z_{i}$ 's and compute $u_{i}$.

## Iterative procedures to find eigenvectors and eigenvalues

Dominant eigenvalue: if a symmetric matrix $\mathrm{A}_{\mathrm{n} \times \mathrm{n}}$ of rank r has eigenvalues $\left\{\lambda_{1} \lambda_{2} \ldots \lambda_{\mathrm{n}}\right\}$, where

$$
\left|\lambda_{1}\right|>\left|\lambda_{2}\right| \geq \ldots \geq\left|\lambda_{n-1}\right| \geq\left|\lambda_{n}\right|
$$

then, $\lambda_{1}$ is called the dominant eigenvalue of $A$.

1) Power method (or iterative method) to approximate the dominant eigenvector ( $\mathrm{v}_{\mathbf{1}}$ ) and the dominate eigenvalue $\left(\lambda_{1}\right)$ of a diagonalizable matrix $A$.
(a) Arbitrarily select a vector, e.g., $\mathrm{x}_{0}$, to be the first approximation to the dominant eigenvector $\mathrm{v}_{1}$.
(b) Compute $\widetilde{\mathrm{V}}_{1(1)}=\mathrm{A} \widetilde{\mathrm{V}}_{1(0)}$ and scale it down, i.e., divide each element of $\widetilde{\mathrm{V}}_{1(1)}$ by its largest element.
(c) Compute $\widetilde{\mathrm{V}}_{1(2)}=\mathrm{A} \widetilde{\mathrm{V}}_{1(1)}\left(=\mathrm{A}^{2} \widetilde{\mathrm{~V}}_{1(0)}\right)$ and scale it down.
(d) Compute the first approximation to the dominant eigenvalue as follows:

$$
\lambda_{1} \approx \frac{\widetilde{\mathrm{v}}_{1(1)}, \widetilde{\mathrm{v}}_{1(2)}}{\widetilde{\mathrm{V}}_{1(1)}, \widetilde{\mathrm{V}}_{1(1)}}=\widetilde{\lambda}_{1(1)}
$$

This computation is based on the equality

$$
\frac{\mathrm{v}_{1}^{\prime}{ }^{\prime} \mathrm{Av}_{1}}{\mathrm{v}_{1}{ }^{\prime} \mathrm{v}_{1}}=\frac{\mathrm{v}_{1}{ }^{\prime} \lambda \mathrm{v}_{1}}{\mathrm{v}_{1}{ }^{\prime} \mathrm{v}_{1}}=\frac{\lambda \mathrm{v}_{1}^{\prime}{ }^{\prime} \mathrm{v}_{1}}{\mathrm{v}_{1}{ }^{\prime} \mathrm{v}_{1}}=\lambda
$$

Thus,

$$
\lambda_{1} \approx \frac{\widetilde{\mathrm{v}}_{1(1)}{ }^{\prime} \mathrm{A} \widetilde{\mathrm{~V}}_{1(1)}}{\widetilde{\mathrm{v}}_{1(1)} \widetilde{\mathrm{V}}_{1(1)}}=\frac{\widetilde{\mathrm{v}}_{1(1)}, \lambda_{1} \widetilde{\mathrm{v}}_{1(1)}}{\widetilde{\mathrm{v}}_{1(1)} \widetilde{\mathrm{v}}_{1(1)}}=\lambda_{1} \mathrm{~V}_{1(1)}, \widetilde{\mathrm{V}}_{1(1)}=\tilde{\lambda}_{1(1)}
$$

(e) Repeat the computations

$$
\tilde{\lambda}_{1(\mathrm{i})}=\frac{\widetilde{\mathrm{v}}_{1(\mathrm{i}-1)}}{\widetilde{\mathrm{V}}_{1(\mathrm{i}-1)}, \widetilde{\mathrm{v}}_{1(\mathrm{i})}}
$$

until the convergence criterion is met. Such convergence criterion could be:
(i) The estimated relative error:

$$
\left|\frac{\tilde{\lambda}_{1 \mathrm{i})}-\tilde{\lambda}_{1(\mathrm{i}-1)}}{\tilde{\lambda}_{1(\mathrm{i})}}\right|<\mathrm{E}
$$

i.e., the absolute value of the difference between the estimates of $\lambda_{1}$ in the $i^{\text {th }}$ and $(i-1)^{\text {th }}$ iterations relative to the estimate of $\lambda_{1}$ in the $\mathrm{i}^{\text {th }}$ iteration is less than a chosen number E . For instance, $\mathrm{E}=$ 0.00001 .
(ii) The estimated percentage error:

$$
\left|\frac{\tilde{\lambda}_{1 \mathrm{i})}-\tilde{\lambda}_{1(\mathrm{i}-1)}}{\tilde{\lambda}_{1(\mathrm{i})}}\right| * 100 \leq 100 \mathrm{E}
$$

(f) At convergence after p iterations, the vector $\mathrm{x}_{\mathrm{p}}$ is a good approximation to the dominant eigenvector $\mathrm{v}_{1}$, and the scalar $\lambda_{1(\mathrm{p})}$ is a good approximation to the dominant eigenvalue $\lambda_{1}$.

Proof:
Let A be an $\mathrm{n} \times \mathrm{n}$ diagonalizable matrix of rank r . If A is diagonalizable, A has a set of n independent eigenvectors $\left\{\mathrm{v}_{1}, \mathrm{v}_{2}, \ldots, \mathrm{v}_{\mathrm{n}}\right\}$. To see this, note that $\mathrm{AV}=\mathrm{VD}$, where $\mathrm{D}=\operatorname{diag}\left\{\lambda_{\mathrm{i}}\right\}$ and $\mathrm{V}=\left[\mathrm{v}_{1} \mathrm{~V}_{2} \ldots \mathrm{v}_{\mathrm{n}}\right]$ (for proof see Searle, 1966, pg. 168, or Anton, 1981, pg. 269).

Let $\left\{\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\right\}$ be the set of eigenvalues of $A$ and assume that

$$
\left|\lambda_{1}\right|>\left|\lambda_{2}\right| \geq \ldots \geq\left|\lambda_{n}\right|
$$

By theorem 9(a) of Anton (1981, pg. 155), the set of linearly independent eigenvectors of matrix A, $\left\{\mathrm{v}_{1}, \mathrm{v}_{2}, \ldots, \mathrm{v}_{\mathrm{n}}\right\}$ form a basis for $\mathrm{R}^{\mathrm{n}}$. Thus, an arbitrary vector $\mathrm{x}_{0}$ in $\mathrm{R}^{\mathrm{n}}$ can be expressed as a linear combination of $\mathrm{v}_{1}, \mathrm{v}_{2}, \ldots, \mathrm{v}_{\mathrm{n}}$, i.e.,

$$
\mathrm{x}_{0}=\mathrm{m}_{1} \mathrm{v}_{1}+\mathrm{m}_{2} \mathrm{v}_{2}+\ldots+\mathrm{m}_{\mathrm{n}} \mathrm{v}_{\mathrm{n}}
$$

But

$$
\begin{aligned}
\mathrm{Ax}_{0} & =\mathrm{m}_{1} A v_{1}+\mathrm{m}_{2} A v_{2}+\ldots+m_{n} A v_{n} \\
& =m_{1} \lambda_{1} v_{1}+m_{2} \lambda_{2} \mathrm{v}_{2}+\ldots+m_{n} \lambda_{\mathrm{n}} \mathrm{v}_{\mathrm{n}}
\end{aligned}
$$

and

$$
\begin{aligned}
\mathrm{A}\left(\mathrm{Ax}_{0}\right) & =\mathrm{m}_{1} \lambda_{1} A v_{1}+\mathrm{m}_{2} \lambda \lambda_{2} A v_{2}+\ldots+\mathrm{m}_{\mathrm{n}} \lambda_{\mathrm{n}} \mathrm{Av}_{\mathrm{n}} \\
\mathrm{~A}^{2} \mathrm{x}_{0} & =\mathrm{m}_{1} \lambda \mathrm{v}_{1}+\mathrm{m}_{2} \lambda \mathrm{v}_{2}+\ldots+\mathrm{m}_{\mathrm{n}} \lambda \mathrm{v}_{\mathrm{n}} \\
& \vdots \\
& \\
\mathrm{~A}^{\mathrm{p}} \mathrm{x}_{0} & =\mathrm{m}_{1} \lambda \mathrm{v}_{1}+\mathrm{m}_{2} \lambda \mathrm{v}_{2}+\ldots+\mathrm{m}_{\mathrm{n}} \lambda \mathrm{v}_{\mathrm{n}} .
\end{aligned}
$$

Because $\lambda_{1} \neq 0$,

$$
\mathrm{A}^{\mathrm{p}} \mathrm{x}_{0}=\lambda_{1}^{\mathrm{p}}\left[\mathrm{~m}_{1} \mathrm{v}_{1}+\mathrm{m}_{2}\left(\frac{\lambda_{2}}{\lambda_{1}}\right)^{\mathrm{p}} \mathrm{v}_{2}+\ldots+\mathrm{m}_{\mathrm{n}}\left(\frac{\lambda_{2}}{\lambda_{1}}\right)^{\mathrm{p}} \mathrm{v}_{\mathrm{n}}\right]
$$

Also, as $\mathrm{p} \rightarrow \infty,\left\{\left(\frac{\lambda_{2}}{\lambda_{1}}\right)^{\mathrm{p}}, \ldots,\left(\frac{\lambda_{\mathrm{n}}}{\lambda_{1}}\right)^{\mathrm{p}}\right\} \rightarrow 0 \quad$ because $\quad\left|\lambda_{1}\right|>\left|\lambda_{2}\right| \geq \ldots \geq\left|\lambda_{\mathrm{n}}\right|$.
Thus,

$$
\mathrm{A}^{\mathrm{p}} \mathrm{x}_{0} \approx \lambda \mathrm{~m}_{1} \mathrm{~V}_{1} \text { as } \mathrm{p} \rightarrow \infty .
$$

If $\mathrm{m}_{1} \neq 0$, then $\left(\lambda \mathrm{m}_{1}\right) \mathrm{v}_{1}$ is a multiple of the dominant eigenvector $\mathrm{v}_{1}$. Thus, $\lambda \mathrm{m}_{1} \mathrm{v}_{1}$ is also a
dominant eigenvector. Therefore, as p increases, $\mathrm{A}^{\mathrm{p}} \mathrm{x}_{0}$ becomes an increasingly better estimate of a dominant eigenvector.

## 2) Deflation method to approximate nondominant eigenvectors and eigenvalues

The deflation method is based on the following theorem (Anton, 1981, pg. 336; Searle, 1966, pg. 187).

Theorem: Let A be a symmetric $n \times n$ matrix of rank $r$ with eigenvalues $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}$. If $v_{1}$ is an eigenvector of A corresponding to $\lambda_{1}$, and $\left[\mathrm{v}_{1}{ }^{\prime} \mathrm{v}_{1}\right]^{1 / 2}=1$, i.e., $\mathrm{v}_{1}$ has unit length, then:
(i) The matrix $\mathrm{A}_{1}=\mathrm{A}-\lambda_{1} \mathrm{~V}_{1} \mathrm{~V}_{1}{ }^{\prime}$ has eigenvalues $0, \lambda_{2}, \lambda_{3}, \ldots, \lambda_{\mathrm{n}}$.
(ii) The eigenvectors of $\mathrm{A}_{1}$ corresponding to $\lambda_{2}, \lambda_{3}, \ldots, \lambda_{\mathrm{n}}$ are also eigenvectors for $\lambda_{2}, \lambda_{3}, \ldots, \lambda_{\mathrm{n}}$ in A.

Proof: see Searle, 1966, pg. 187.
The deflection method also rests on the assumption that

$$
\left|\lambda_{1}\right|>\left|\lambda_{2}\right|>\left|\lambda_{3}\right|>\ldots \geq\left|\lambda_{\mathrm{n}}\right| .
$$

The procedure of deflation is as follows:
(a) Compute $\mathrm{A}_{1}$ using the expression:

$$
\mathrm{A}_{1}=\mathrm{A}-\widetilde{\lambda}_{1(\mathrm{p})} \widetilde{\mathrm{Z}}_{1(\mathrm{p})} \widetilde{\mathrm{Z}}_{1(\mathrm{p})}
$$

where

$$
\widetilde{\mathrm{Z}}_{1(\mathrm{p})}=\frac{\widetilde{\mathrm{V}}_{1(\mathrm{p})}}{\left[\widetilde{\mathrm{v}}_{1(\mathrm{p})} \widetilde{\mathrm{V}}_{1(\mathrm{p})}\right]^{1 / 2}}
$$

(b) Estimate the dominant eigenvector $\left(\mathrm{v}_{2}\right)$ and the dominant eigenvalue $\left(\lambda_{2}\right)$ of $\mathrm{A}_{1}$ using the power method, i.e., obtain $\widetilde{\mathrm{V}}_{2(\mathrm{p})}$ and $\tilde{\lambda}_{2(\mathrm{p})}$.
(c) Repeat steps (a) and (b) for $\mathrm{A}_{\mathrm{i}}, \mathrm{i}=3, \ldots$, last dominant eigenvector and eigenvalue.

Warning: because $\lambda_{i}$ and $v_{i}$ are estimated iteratively, rounding errors accumulate quickly. Thus, the deflation method is recommended to estimate only two or three eigenvectors and eigenvalues (Anton, 1981, pg. 338).
