## ANIMAL BREEDING NOTES

## CHAPTER 8

## BEST PREDICTION

## Derivation of the Best Predictor (BP)

Let $g=\left[\begin{array}{llll}g_{1} & g_{2} & \ldots & g_{\mathrm{p}}\end{array}\right]^{\prime}$ be a vector of unobservable random variables jointly distributed with an observable random vector $\mathrm{y}=\left[\begin{array}{llll}\mathrm{y}_{1} & \mathrm{y}_{2} & \ldots & \mathrm{y}_{\mathrm{n}}\end{array}\right]^{\prime}$.

We want to predict g using y . Let $\mathrm{h}(\mathrm{y})$ denote the predictor, i.e., if y is observed to be equal to $\dot{\mathrm{y}}$, then $\mathrm{h}(\dot{\mathrm{y}})$ will be the prediction for g . Also, we want to choose the function $\mathbf{h}$ such that $\mathbf{h}(\mathbf{y})$ tends to be close to $g$. One possible criterion for closeness is to choose $h(y)$ such that it minimizes the mean square error of prediction (MSEP), i.e., we want

$$
\mathrm{E}\left[(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g})\right] \rightarrow 0
$$

where $G$ is any symmetric positive definite matrix, e.g., $G=\operatorname{cov}\left(g, g^{\prime}\right)$. Under this criterion the best predictor (BP) of $\mathbf{g}$ is:

$$
\mathbf{h}(\mathbf{y})=\mathbf{E}[\mathbf{g} \mid \mathbf{y}] \equiv \hat{\mathrm{g}}
$$

the conditional mean of g given $y$.
Proof:

$$
\begin{aligned}
\mathrm{E}\left[(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g})\right] & =\int_{y} \int_{g}(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g}) \mathrm{f}(\mathrm{y}, \mathrm{~g}) \mathrm{dg} \mathrm{dy} \\
& =\int_{\mathrm{y}}\left[\int_{\mathrm{g}}(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g}) \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg}\right] \mathrm{f}(\mathrm{y}) \mathrm{dy}
\end{aligned}
$$

$\Rightarrow$ to minimize the E[] with respect to $\mathrm{h}(\mathrm{y})$ requires to minimize only the integral over g (in brackets), because minimizing for each y implies minimizing over all y's, so:

$$
\begin{align*}
& \frac{\partial}{\partial \mathrm{h}(\mathrm{y})}\left[\int_{\mathrm{g}}(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g}) \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg}\right]  \tag{8-2}\\
& =\int_{\mathrm{g}} \frac{\partial}{\partial \mathrm{~h}(\mathrm{y})}\left[(\mathrm{h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g}) \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg}\right] \\
& \\
& \left.=\int_{\mathrm{g}} \frac{\partial}{\partial \mathrm{~h}(\mathrm{y})}\left[\mathrm{h}(\mathrm{y})^{\prime} \mathrm{Gh}(\mathrm{y})-2 \mathrm{~h}(\mathrm{y})^{\prime} \mathrm{Gg}+\mathrm{g}^{\prime} \mathrm{Gg}\right) \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg}\right] \\
& =\quad \int_{\mathrm{g}}(2 \mathrm{Gh}(\mathrm{y})-2 \mathrm{Gg}) \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg}=0 \\
& \Rightarrow \quad 2 \mathrm{Gh}(\mathrm{y}) \mathrm{I}_{\mathrm{g}} \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg} \quad=2 \mathrm{G} \mathrm{~J}_{g} g \mathrm{f}(\mathrm{~g} \mid \mathrm{y}) \mathrm{dg}
\end{align*}
$$

But $\mathrm{J}_{\mathrm{g}} \mathrm{f}(\mathrm{g} \mid \mathrm{y}) \mathrm{dg}=1$,
$\Rightarrow \quad \mathrm{h}(\mathrm{y})=\mathrm{J}_{\mathrm{g}} \mathrm{gf}(\mathrm{g} \mid \mathrm{y}) \mathrm{dg}=\mathrm{E}[\mathrm{g} \mid \mathrm{y}]=\hat{\mathrm{g}}$
$\Rightarrow \quad$ the BP of $\mathrm{g}, \hat{\mathrm{g}}=\mathrm{E}_{\mathrm{g}}[\mathrm{g} \mid \mathrm{y}]$, the conditional mean of g given y .

## Remarks:

(1) $\hat{g}=E[g \mid y]$ hold for all density functions, and
(2) $\quad \hat{g}=E[g \mid y]$ does not depend on $G$.

Two useful results and an alternative proof for BP of $\mathbf{g}=\mathbf{E}[\mathbf{g} \mid \mathbf{y}]$.
(a) Expectation of a quadratic form

Let $\mathrm{x}_{\mathrm{px} 1}$ be a random vector and $\mathrm{b}_{\mathrm{px} 1}$ be one of its realized vectors, where b is a vector other than the mean vector $\mu_{\mathrm{px} 1}$. Then, the expected value of the ellipsoid centered at b can be written as:

$$
\mathbf{E}_{\mathrm{x}}\left[(\mathrm{x}-\mathrm{b})^{\prime} \mathbf{A}(\mathrm{x}-\mathrm{b})\right]=\operatorname{tr}(\mathbf{A} \operatorname{var}(\mathbf{x}))+(\mu-b)^{\prime} \mathbf{A}(\mu-\mathrm{b})
$$

where A is any s.p.d. matrix.
Proof:

$$
\begin{align*}
\mathrm{E}_{\mathrm{x}}\left[(\mathrm{x}-\mathrm{b})^{\prime} \mathrm{A}(\mathrm{x}-\mathrm{b})\right] & =\mathrm{E}_{\mathrm{x}}\left[(\mathrm{x}-\mu+\mu-\mathrm{b})^{\prime} \mathrm{A}(\mathrm{x}-\mu+\mu-\mathrm{b})\right]  \tag{8-3}\\
& =\mathrm{E}_{\mathrm{x}}\left[(\mathrm{x}-\mu)^{\prime} \mathrm{A}(\mathrm{x}-\mu)+(\mu-\mathrm{b})^{\prime} \mathrm{A}(\mu-\mathrm{b})\right]
\end{align*}
$$

Since a quadratic form is a scalar, it equals its own trace, thus,

$$
\begin{aligned}
\mathrm{E}_{\mathrm{x}}\left[(\mathrm{x}-\mathrm{b})^{\prime} \mathrm{A}(\mathrm{x}-\mathrm{b})\right] & =\mathrm{E}_{\mathrm{x}} \operatorname{tr}\left[\mathrm{~A}(\mathrm{x}-\mu)(\mathrm{x}-\mu)^{\prime}\right]+\mathrm{E}_{\mathrm{x}}\left[(\mu-\mathrm{b})^{\prime} \mathrm{A}(\mu-\mathrm{b})\right] \\
& =\operatorname{tr}\left[\mathrm{A} \mathrm{E}_{\mathrm{x}}\left[(\mathrm{x}-\mu)(\mathrm{x}-\mu)^{\prime}\right]\right]+(\mu-\mathrm{b})^{\prime} \mathrm{A}(\mu-\mathrm{b}) \\
& =\operatorname{tr}(\mathrm{A} \operatorname{var}(\mathrm{x})]+(\mu-\mathrm{b})^{\prime} \mathrm{A}(\mu-\mathrm{b})
\end{aligned}
$$

## (b) Computation of variances by conditioning

Let $\mathrm{x}_{\mathrm{p} \times 1}$ be a random vector and $\mu_{\mathrm{p} \times 1}$ its mean vector. If the vector x is conditioned on another random vector $y$, then, the variance of $x$ can be written as the sum of the expected variance of $x$ given $y$ plus the variance of the expected value of $x$ given $y$, i.e,

$$
\operatorname{var}(\mathbf{x})=\mathbf{E}_{\mathbf{y}}\left[\operatorname{var}_{\mathbf{x}}(\mathbf{x} \mid \mathbf{y})\right]+\operatorname{var}_{\mathbf{y}}\left(\mathbf{E}_{\mathbf{x}}[\mathbf{x} \mid \mathbf{y}]\right)
$$

Proof:

$$
\begin{aligned}
\operatorname{var}(x)= & E\left[(x-\mu)(x-\mu)^{\prime}\right] \\
= & E_{y}\left[E\left[(x-\mu)(x-\mu)^{\prime} \mid y\right]\right] \\
= & E_{y}\left[E\left[(x-E[x \mid y]+E[x \mid y]-\mu)(x-E[x \mid y]+E[x \mid y]-\mu)^{\prime} \mid y\right]\right] \\
= & E_{y}\left[E \left[\left(x-E[x \mid y]\left(x-E[x \mid y]^{\prime} \mid y\right]\right.\right.\right. \\
& +2 E\left[(x-E[x \mid y])(E[x \mid y]-\mu)^{\prime} \mid y\right] \\
& \left.+E\left[(E[x \mid y]-\mu)(E[x \mid y]-\mu)^{\prime} \mid y\right]\right]
\end{aligned}
$$

The first term of $\operatorname{var}(\mathrm{x})$ is the expected variance of x given y :

$$
\begin{aligned}
& =E_{y}\left[E\left[x x^{\prime} \mid y\right]-2(E[x \mid y])^{2}+(E[x \mid y])^{2}\right] \\
& =E_{y}\left[\operatorname{var}_{x}(x \mid y)\right]
\end{aligned}
$$

The second term of $\operatorname{var}(\mathrm{x})$ is equal to zero:

$$
\begin{aligned}
& =2 \mathrm{E}_{\mathrm{y}}\left[\left(\mathrm{E}[(\mathrm{x} \mid \mathrm{y}])^{2}-\mathrm{E}[\mathrm{x} \mid \mathrm{y}] \mu^{\prime}-(\mathrm{E}[\mathrm{x} \mid \mathrm{y}])^{2}+\mathrm{E}[\mathrm{x} \mid \mathrm{y}] \mu^{\prime}\right]\right. \\
& =0
\end{aligned}
$$

The third term of $\operatorname{var}(\mathrm{x})$ is the variance of the expected value of x given y :

$$
\begin{aligned}
& =E_{y}\left[\left(E[(x \mid y])^{2}-E[x \mid y] \mu^{\prime}-\mu(E[x \mid y])^{\prime}+\mu \mu^{\prime}\right]\right. \\
& =E_{y}\left[\left(E[(x \mid y]-\mu)(E[x \mid y]-\mu)^{\prime}\right]\right. \\
& =E_{y}\left[\operatorname{var}_{y}\left(E_{x}[x \mid y]\right)\right] \\
& =\operatorname{var}_{y}\left(E_{x}[x \mid y]\right)
\end{aligned}
$$

## (c) Alternative proof for BP of $\mathbf{g}=\mathrm{E}[\mathrm{g} \mid \mathrm{y}]$

The MSEP of $\mathrm{h}(\mathrm{y})$ can be written, using result (a), as follows:

$$
\begin{aligned}
\mathrm{E}_{\mathrm{y}}\left[(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g})\right]= & \operatorname{trG}\left\{\mathrm{E}_{\mathrm{y}}\left[(\mathrm{~h}(\mathrm{y})-\mathrm{g})(\mathrm{h}(\mathrm{y})-\mathrm{g})^{\prime}\right]\right\} \\
= & \operatorname{tr~} \mathrm{G}\{\operatorname{var}(\mathrm{~h}(\mathrm{y})-\mathrm{g}) \\
& +\left(\mathrm{E}_{\mathrm{y}}[\mathrm{~h}(\mathrm{y}]-\mathrm{g})\left(\mathrm{E}_{\mathrm{y}}[\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime}\right]\right\}
\end{aligned}
$$

By result (b)

$$
\operatorname{var}(\mathrm{h}(\mathrm{y})-\mathrm{g})=\mathrm{E}_{\mathrm{y}}\left[\operatorname{var}_{\mathrm{g}}((\mathrm{~h}(\mathrm{y})-\mathrm{g}) \mid \mathrm{y})\right]+\operatorname{var}_{\mathrm{y}}\left(\mathrm{E}_{\mathrm{g}}[(\mathrm{~h}(\mathrm{y})-\mathrm{g}) \mid \mathrm{y}]\right)
$$

where

$$
\begin{aligned}
E_{y}\left[\operatorname{var}_{g}((h(y)-g) \mid y)\right] & =E_{y}\left[\operatorname{var}_{g}(g \mid y)\right], \text { and } \\
\operatorname{var}_{y}\left(E_{g}[(h(y)-g \mid y])\right. & =\operatorname{var}_{y}\left(h(y)-E_{g}[g \mid y]\right)
\end{aligned}
$$

because $\mathrm{h}(\mathrm{y}) \mid \mathrm{y}$ is a constant.
Thus,

$$
\operatorname{var}(\mathrm{h}(\mathrm{y})-\mathrm{g})=\mathrm{E}_{\mathrm{y}}[\operatorname{var}(\mathrm{~g} \mid \mathrm{y})]+\operatorname{var}\left(\mathrm{h}(\mathrm{y})-\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right)
$$

and the MSEP of $\mathrm{h}(\mathrm{y})$ is:

$$
\mathrm{E}_{\mathrm{y}}\left[(\mathrm{~h}(\mathrm{y})-\mathrm{g})^{\prime} \mathrm{G}(\mathrm{~h}(\mathrm{y})-\mathrm{g})\right] \quad=\operatorname{tr} \mathrm{G}\left\{\mathrm{E}_{\mathrm{y}}\left[\operatorname{var}_{\mathrm{g}}(\mathrm{~g} \mid \mathrm{y})\right]+\operatorname{var}_{\mathrm{g}}\left(\mathrm{~h}(\mathrm{y})-\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right)\right.
$$

$$
\begin{equation*}
\left.\left.+\left(\mathrm{E}_{\mathrm{y}}[\mathrm{~h}(\mathrm{y})]-\mathrm{g}\right)\left(\mathrm{E}_{\mathrm{y}}[\mathrm{~h}(\mathrm{y})]-\mathrm{g}\right)^{\prime}\right]\right\} \tag{8-5}
\end{equation*}
$$

Because the first and the third terms of the MSEP of $\mathrm{h}(\mathrm{y})$ are constants, to minimize the MSEP of $\mathrm{h}(\mathrm{y})$ we only need to minimize:

$$
\operatorname{var}\left(\mathrm{h}(\mathrm{y})-\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right)
$$

i.e., we want this term to go to zero.

Clearly,

$$
\operatorname{var}\left(h(y)-E_{g}[g \mid y]\right)=0 \quad \text { if } h(y)=E_{g}[g \mid y]
$$

$\Rightarrow \quad$ the MSEP of $\mathrm{h}(\mathrm{y})$ is minimized if $\mathrm{h}(\mathrm{y})$ is equal to the conditional mean of g given y , and
$\Rightarrow \quad$ the BP of g is $E[g \mid y] \equiv \hat{g}$.
As a consequence of $h(y)$ being equal to $E[g \mid y]$ we have that:
(i)

$$
\begin{aligned}
\left(E_{y}[h(y)-g]\right)\left(E_{y}[h(y)-g]\right)^{\prime} & =E_{y}\left[\left(E_{g}[h(y)-g] E_{g}[h(y)-g]\right) \mid y\right] \\
& =E_{y}\left[\left(h(y)-E_{g}[g \mid y]\right)\left(h(y)-E_{g}[g \mid y]\right)\right] \\
& =0 \quad \text { when } h(y)=E_{g}[g \mid y]
\end{aligned}
$$

$\Rightarrow \quad$ the BP of g is unbiased.
(ii) $\quad \mathrm{E}_{\mathrm{y}}\left[(\mathrm{h}(\mathrm{y})-\mathrm{g})^{\prime}(\mathrm{h}(\mathrm{y})-\mathrm{g})\right]=\operatorname{tr}\{\operatorname{var}(\mathrm{h}(\mathrm{y})-\mathrm{g})\}$

$$
=\operatorname{tr}\left\{\mathrm{E}_{\mathrm{y}}[\operatorname{var}(\mathrm{~g} \mid \mathrm{y})]\right\} \quad \text { when } \mathrm{h}(\mathrm{y})=\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]
$$

$\Rightarrow \quad$ the MSEP of $h(y)=$ the error variance of prediction (EVP) of $h(y)$.

## Properties of the best predictor

[1] $\quad \mathrm{E}_{\mathrm{y}}[\hat{\mathrm{g}}]=\mathrm{E}_{\mathrm{y}}\left[\mathrm{E}_{\mathrm{g}}[\mathrm{g} \mid \mathrm{y}]\right]=\mathrm{E}[\mathrm{g}]$
$\Rightarrow \quad$ the BP is unbiased although it was not a condition in its development
$\Rightarrow \quad$ the BP minimizes the error variance of prediction $(\mathrm{EVP})$ of $\hat{\mathrm{g}}$ because $\mathrm{E}[\hat{\mathrm{g}}-\mathrm{g}]=0$.
[2] $\quad \operatorname{var}(\hat{g}-\mathrm{g}) \quad=\mathrm{E}_{\mathrm{y}}[\operatorname{var}(\mathrm{g} \mid \mathrm{y})]$
Proof:

$$
\begin{aligned}
\operatorname{var}(\hat{g}-g) & =E_{y}\left[(\hat{g}-g)(\hat{g}-g)^{\prime}\right] \\
& =E_{y}\left[\hat{g} \hat{g}^{\prime}-\hat{g} g^{\prime}-g \hat{g}^{\prime}+g g^{\prime}\right] \\
& =E_{y}\left[E_{g \mid y}\left[\left(\hat{g} \hat{g}^{\prime}-\hat{g} g^{\prime}-g \hat{g}^{\prime}+g g^{\prime}\right) \mid y\right]\right] \\
& =E_{y}\left[E_{g}[g \mid y] E_{g}[g \mid y]^{\prime}-E_{g}[g \mid y] E_{g}[g \mid y]^{\prime}-E_{g}[g \mid y] E_{g}[g \mid y]^{\prime}+E_{g}\left[g g^{\prime} \mid y\right]\right] \\
& =E_{y}\left[E_{g}\left[g^{\prime} \mid y\right]-E_{g}[g \mid y] E_{g}[g \mid y]^{\prime}\right] \\
& =E_{y}\left[\operatorname{var}_{g}(g \mid y)\right]
\end{aligned}
$$

$\Rightarrow \quad$ the EVP of $\hat{g}$ is the weighted average of the variances of the elements of random vector $g$ over all possible realizations of random vector y .
[3] $\operatorname{var}(\hat{g})=\operatorname{var}_{y}\left(E_{g}[g \mid y]\right)$
Proof:

$$
\begin{aligned}
\operatorname{var}(\hat{\mathrm{g}}) & =\mathrm{E}_{\mathrm{y}}\left[\operatorname{var}_{\mathrm{g}}(\hat{\mathrm{~g}} \mid \mathrm{y})\right]+\operatorname{var}_{\mathrm{y}}(\mathrm{E}[\hat{\mathrm{~g}} \mid \mathrm{y}]) \\
& =\mathrm{E}_{\mathrm{y}}\left[\operatorname{var}_{\mathrm{g}}\left(\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right)\right]+\operatorname{var}_{\mathrm{y}}\left(\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right) \\
& =\mathrm{E}_{\mathrm{y}}[0]+\operatorname{var}_{\mathrm{y}}\left(\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right) \\
& =\operatorname{var}_{\mathrm{y}}\left(\mathrm{E}_{\mathrm{g}}[\mathrm{~g} \mid \mathrm{y}]\right)
\end{aligned}
$$

$\Rightarrow \quad$ the $\operatorname{var}(\hat{\mathrm{g}})$ is equal to the variance of the expected value of g given y.
[4] $\quad \operatorname{var}(\mathrm{g})=\mathrm{E}_{\mathrm{y}}\left[\operatorname{var}_{\mathrm{g}}(\mathrm{g} \mid \mathrm{y})\right]+\operatorname{var}_{\mathrm{y}}\left(\mathrm{E}_{\mathrm{g}}[\mathrm{g} \mid \mathrm{y}]\right)$
$\operatorname{var}(\mathrm{g})=\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g})+\operatorname{var}(\hat{\mathrm{g}}) \quad$ by [2] and [3]
$\Rightarrow \quad \operatorname{var}(\hat{g}-\mathrm{g}) \quad=\quad \operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}})$
[5] $\quad \operatorname{cov}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right)=\operatorname{var}(\hat{\mathrm{g}})$

Proof:
Version 1:

$$
\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g})=\operatorname{var}(\hat{\mathrm{g}})+\operatorname{var}(\mathrm{g})-2 \operatorname{cov}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right)
$$

But,

$$
\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g}) \quad=\operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}})
$$

Thus,

$$
\begin{aligned}
\operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}}) & =\operatorname{var}(\hat{\mathrm{g}})+\operatorname{var}(\mathrm{g})-2 \operatorname{cov}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) \\
\Rightarrow \quad \operatorname{cov}\left(\hat{\mathrm{g}}, \mathrm{~g}^{\prime}\right) & =\operatorname{var}(\hat{\mathrm{g}})
\end{aligned}
$$

Version 2:

$$
\begin{aligned}
\operatorname{cov}\left(\hat{\mathrm{g}}, \mathrm{~g}^{\prime}\right) & =\mathrm{E}\left[\hat{\mathrm{~g}} \mathrm{~g}^{\prime}\right]-\mathrm{E}[\hat{\mathrm{~g}}] \mathrm{E}[\mathrm{~g}] \\
& =\mathrm{E}\left[\hat{\mathrm{~g}} \mathrm{~g}^{\prime}\right]-(\mathrm{E}[\hat{\mathrm{~g}}])^{2} \quad \text { by }[1]
\end{aligned}
$$

and

$$
\begin{aligned}
\mathrm{E}\left[\hat{\mathrm{~g}} \mathrm{~g}^{\prime}\right] & =\int_{y} \int_{g} \hat{\mathrm{~g}} \mathrm{~g}^{\prime} \mathrm{f}_{\mathrm{yg}}(\mathrm{y}, \mathrm{~g}) \mathrm{dg} \mathrm{dy} \\
& =\int_{y} \hat{g}\left[\int_{g} g f_{g_{y} y}(g \mid y) d g\right] f_{y}(y) d y \\
& =\int_{y} \hat{\mathrm{~g}} \mathrm{E}[\mathrm{~g} \mid \mathrm{y}] \mathrm{f}_{y}(\mathrm{y}) \mathrm{dy} \\
& =\int_{y} \hat{\mathrm{~g}} \hat{\mathrm{~g}}^{\prime} \mathrm{f}_{\mathrm{y}}(\mathrm{y}) \mathrm{dy} \\
& =\mathrm{E}\left[\hat{\mathrm{~g}} \hat{\mathrm{~g}}^{\prime}\right] \\
\Rightarrow \operatorname{cov}\left(\hat{\mathrm{g}}, \mathrm{~g}^{\prime}\right) & =\mathrm{E}\left[\hat{\mathrm{~g}} \hat{\mathrm{~g}}^{\prime}\right]-(\mathrm{E}[\hat{\mathrm{~g}}])^{2} \\
\Rightarrow \operatorname{cov}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) & =\operatorname{var}(\hat{\mathrm{g}})
\end{aligned}
$$

[6] $\quad \mathrm{r}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right)=\left[\operatorname{cov}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right)\right][\operatorname{var}(\hat{\mathrm{g}}) \operatorname{var}(\mathrm{g})]^{-1 / 2}$

Note: if $\operatorname{var}(\mathrm{g})$ and $\operatorname{var}(\hat{\mathrm{g}})$ are positive definite (Property (6), Chapter 4), there are orthogonal matrices L and M , such that

$$
[\operatorname{var}(\mathrm{g})]^{-1 / 2}=\operatorname{diag}\left\{\left(\lambda \mathrm{g}_{\mathrm{i}}\right)^{-1 / 2}\right\} \mathrm{L}^{\prime}
$$

and

$$
[\operatorname{var}(\hat{\mathrm{g}})]^{-1 / 2}=\operatorname{diag}\left\{\left(\lambda \hat{\mathrm{g}}_{\mathrm{i}}\right)^{-1 / 2}\right\} \mathrm{M}^{\prime}
$$

where the $\lambda \mathrm{g}_{\mathrm{i}}$ and the $\lambda \hat{\mathrm{g}}_{\mathrm{i}}$ are the eigenvalues of the matrices $\operatorname{var}(\mathrm{g})$ and $\operatorname{var}(\hat{g})$ and L and M are the corresponding matrices of eigenvectors. But,

$$
\operatorname{cov}\left(\hat{g}, g^{\prime}\right)=\operatorname{var}(\hat{\mathrm{g}})
$$

thus,

$$
\begin{aligned}
\mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) & =[\operatorname{var}(\hat{\mathrm{g}})]^{1 / 2}[\operatorname{var}(\mathrm{~g})]^{-1 / 2} \\
& =\operatorname{diag}\left\{\frac{\lambda \hat{g}_{i}}{\lambda g_{i}}\right\} \mathrm{L}^{\prime} \mathrm{M}
\end{aligned}
$$

$\Rightarrow \quad$ if the eigenvalues of $\operatorname{var}(\hat{\mathrm{g}})$ and $\operatorname{var}(\mathrm{g})$ are the same, M , the inverse of the orthogonal matrix $M^{\prime}$, will also be the inverse of $L^{\prime}$, i.e., $M=L$,
$\Rightarrow \quad r\left(\hat{g}, g^{\prime}\right)$ will be an identity matrix, and
$\Rightarrow \quad r\left(\hat{g}, g^{\prime}\right)$ is maximized if the sets of eigenvalues of the $\operatorname{var}(\hat{\mathrm{g}})$ and $\operatorname{var}(\mathrm{g})$ matrices are identical.

## Also, recall that

$$
\begin{aligned}
\operatorname{var}(\hat{\mathrm{g}}) & =\operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g}) \\
\Rightarrow \quad \mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) & =[\operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g})]^{1 / 2}[\operatorname{var}(\mathrm{~g})]^{-1 / 2}
\end{aligned}
$$

Squaring both sides yields

$$
\begin{align*}
\mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) \mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right)^{\prime} & =\operatorname{var}(\mathrm{g}) / \operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g}) / \operatorname{var}(\mathrm{g})  \tag{8-9}\\
& =\mathrm{I}-\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g}) / \operatorname{var}(\mathrm{g})
\end{align*}
$$

and taking square roots of both sides gives

$$
\begin{aligned}
\mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) & =[\mathrm{I}-\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g}) / \operatorname{var}(\mathrm{g})]^{-1 / 2} \\
& =\mathrm{I}, \quad \text { if } \operatorname{var}(\hat{\mathrm{g}}-\mathrm{g})=0
\end{aligned}
$$

$\Rightarrow \quad$ because the BP minimizes $\operatorname{var}(\hat{\mathrm{g}}-\mathbf{g})$, it also maximizes $\mathbf{r}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right)$.
[7] $\quad \operatorname{var}(\hat{g}-\mathrm{g}) \quad=\left[\mathrm{I}-\mathrm{r}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right) \mathrm{r}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right)^{\prime}\right] \operatorname{var}(\mathrm{g})$
Proof:

$$
\begin{aligned}
\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g}) & =\operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}}) \\
& =\left[\left[\operatorname{var}(\mathrm{g})[\operatorname{var}(\mathrm{g})]^{-1}-\operatorname{var}(\hat{\mathrm{g}})[\operatorname{var}(\mathrm{g})]^{-1}\right] \operatorname{var}(\mathrm{g})\right.
\end{aligned}
$$

But $r\left(\hat{g}, g^{\prime}\right)=[\operatorname{var}(\hat{g})]^{1 / 2}[\operatorname{var}(\mathrm{~g})]^{-1 / 2}$, thus

$$
\operatorname{var}(\hat{\mathrm{g}}-\mathrm{g})=\left[\mathrm{I}-\mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right) \mathrm{r}\left(\hat{\mathrm{~g}}, \mathrm{~g}^{\prime}\right)^{\prime}\right] \operatorname{var}(\mathrm{g})
$$

## [8] Selection rules:

[8.1] Cochran's rule: select all animals in a population whose

$$
\hat{g}_{i}=\mathrm{E}\left[\mathrm{~g}_{\mathrm{i}} \mid \mathrm{y}_{\mathrm{i}}\right] \geq \mathbf{t}
$$

where $\mathbf{t}$ is a truncation point chosen such that

$$
\mathrm{P}\left\{\mathrm{~g}_{\mathrm{i}}=\mathrm{E}\left[\mathrm{~g}_{\mathrm{i}} \mid \mathrm{y}_{\mathrm{i}}\right] \geq \mathrm{t}\right\}=\mathbf{s}
$$

where $\mathbf{s}$ is the selected fraction of the population, and $y_{i}=\left[y_{1 i} y_{2 i} \ldots y_{n i}\right]^{\prime}$.

## Remarks:

(1) Cochran's rule requires the assumption that the cumulative distribution function of $\hat{\mathrm{g}}_{\mathrm{i}}$ (i.e.,
$\left.\mathrm{E}\left[\mathrm{g}_{\mathrm{i}} \mid \mathrm{y}_{\mathrm{i}}\right]\right)$ is continuous and monotone such that for any selected fraction $\mathrm{s}, 0<\mathbf{s}<1$, there is only one $\mathbf{t}$ that satisfies $\mathrm{P}\left\{\hat{\mathrm{g}}_{\mathrm{i}} \geq \mathbf{t}\right\}=\mathbf{s}$.
(2) If the $\left(g_{i}, y_{i}\right)$ sampled are IID, then selection of animals based on the $E\left[g_{i} \mid y_{i}\right]=\hat{g}_{i}$ maximizes $E_{s}(g)$, the expected genetic value of the animals in the selected fraction $\mathbf{s}$.

Note that IID means that:
(a) animals must have the same amount and type of information, and
(b) animals must be unrelated.
[8.2] Fernando's rule: Select s individuals out of the n animals in the population using

$$
\hat{\mathrm{g}}=\mathbf{E}[\mathbf{g} \mid \mathbf{y}] \text {, where } \mathrm{g}=\left[\begin{array}{lll}
g_{1} & g_{2} \ldots & g_{\mathrm{n}}
\end{array}\right]^{\prime} \text {, and } \mathrm{y}=\left[\begin{array}{llll}
y_{11} & y_{12} & \ldots & y_{n q_{n}}
\end{array}\right] \text {. }
$$

## Remarks:

(1) Fernando's rule makes no assumptions on:
(a) the distribution of $(\mathrm{g} \mid \mathrm{y})$, i.e., it holds for any distribution, and
(b) the quality and quantity of information for individual, i.e., animals may have unequal information and they can be related.
(2) Selection of $s$ out of $n$ animals using $\hat{g}=E[g \mid y]$ maximizes $E_{s}(g)$, the expected genetic value of the s selected individuals.
[9] Drawback of BP: How to compute it?

## Must know:

(a) The conditional distribution of (g|y), and
(b) The parameters of the distribution.

However, when the joint distribution of ( $\mathrm{g}, \mathrm{y}$ ) is multivariate normal, the form of the BP simplifies greatly. In such case,
(a) The conditional mean of $u$ is linear in $y$,
(b) The only parameters needed are the first and second moments, and
(c) BP is identical computationally to the best linear prediction (BLP).

Thus, assume

$$
\left[\begin{array}{l}
y \\
g
\end{array}\right] \sim M V N\left\{\left[\begin{array}{l}
\mu_{y} \\
\mu_{g}
\end{array}\right],\left[\begin{array}{cc}
V & C \\
C^{\prime} & G
\end{array}\right]\right\}
$$

Thus,

$$
(\mathrm{g} \mid \mathrm{y}) \sim \operatorname{MVN}\left\{\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mathrm{y}-\mu_{\mathrm{y}}\right), \mathrm{G}-\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}\right\}
$$

$\Rightarrow \quad \hat{g} \quad=\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mathrm{y}-\mu_{\mathrm{y}}\right)$ under normality.

## Properties of the best predictor under normality

[1] $\quad \mathrm{E}_{\mathrm{y}}[\hat{\mathrm{g}}]=\mathrm{E}_{\mathrm{y}}\left[\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mathrm{y}-\mu_{\mathrm{y}}\right)\right]$

$$
\begin{aligned}
& =\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mu_{\mathrm{y}}-\mu_{\mathrm{y}}\right) \\
& =\mu_{\mathrm{g}} \\
& =\mathrm{E}[\mathrm{~g}] \quad \text { ("weak property of BP"). }
\end{aligned}
$$

[2] $\mathrm{E}[\mathrm{g} \mid \hat{\mathrm{g}}]=\mathrm{E}_{\mathrm{g}}[\mathrm{g} \mid \mathrm{y}]=\hat{\mathrm{g}}$
Proof:

$$
\begin{aligned}
& {\left[\begin{array}{l}
\hat{g} \\
g
\end{array}\right] \sim M V N\left\{\left[\begin{array}{l}
\mu_{g} \\
\mu_{g}
\end{array}\right],\left[\begin{array}{lr}
C^{\prime} V^{-1} C & C^{\prime} V^{-1} C \\
C^{\prime} V^{-1} C & G
\end{array}\right]\right\}} \\
& \operatorname{cov}\left(\hat{\mathrm{g}}, \mathrm{~g}^{\prime}\right) \quad=\operatorname{cov}\left(\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{y}, \mathrm{~g}^{\prime}\right) \\
& =\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}
\end{aligned}
$$

$\Rightarrow \mathrm{E}_{\mathrm{y}}[\mathrm{g} \mid \hat{\mathrm{g}}] \quad=\mu_{\mathrm{g}}+\mathrm{CV}^{-1} \mathrm{C}^{\prime}\left(\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}\right)^{-1}\left(\hat{\mathrm{~g}}-\mathrm{E}_{\mathrm{y}}[\hat{\mathrm{g}}]\right)$

$$
=\mu_{\mathrm{g}}+\left(\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mathrm{y}-\mu_{\mathrm{y}}\right)-\mu_{\mathrm{g}}\right)
$$

$$
=\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mathrm{y}-\mu_{\mathrm{y}}\right)
$$

$$
=E_{g}[\mathrm{~g} \mid \mathrm{y}]
$$

$$
=\hat{\mathrm{g}} \quad(\text { "strong property of BP"). }
$$

[3] $\operatorname{var}(\hat{g}-\mathrm{g})=\operatorname{var}(\mathrm{g})-\operatorname{var}(\hat{\mathrm{g}})$

$$
=\mathrm{G}-\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}
$$

[4] $\operatorname{var}(\hat{g})=\operatorname{var}\left(\mu_{\mathrm{g}}+\mathrm{C}^{\prime} \mathrm{V}^{-1}\left(\mathrm{y}-\mu_{\mathrm{y}}\right)\right)$

$$
=\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{VV}^{-1} \mathrm{C}
$$

$$
=\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}
$$

[5] $\operatorname{cov}\left(\hat{g}, \mathrm{~g}^{\prime}\right) \quad=\operatorname{cov}\left(\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{y}, \mathrm{g}^{\prime}\right)$

$$
=\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}
$$

$$
=\operatorname{var}(\hat{g})
$$

[6] $\quad \mathrm{r}\left(\hat{\mathrm{g}}, \mathrm{g}^{\prime}\right)=[\operatorname{var}(\hat{\mathrm{g}})]^{1 / 2}\left[\operatorname{var}\left(\mathrm{~g}^{\prime}\right)\right]^{-1 / 2}$

$$
=\left[\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{C}\right]^{1 / 2}[\mathrm{G}]^{-1 / 2}
$$

[7] $\quad \operatorname{var}\left(\hat{g}-\mathrm{g}^{\prime}\right) \quad=\left[\mathrm{I}-\mathrm{C}^{\prime} \mathrm{V}^{-1} \mathrm{CG}^{-1}\right] \mathrm{G}$
