Assumptions

(a) \( n_b \) unrelated breeds,
(b) \( k_b \) loci per breed, \( k_b \) arbitrary,
(c) \( r_{bk} \) alleles per locus in breed \( b \), \( r_{bk} \) arbitrary, and
(d) no linkage.

Multibreed Breeding Value

Genetic value of an individual based on the mean genotypic value of its progeny. Because parents pass on their genes (not their genotypes) to their progeny, the mean genotypic value of their progeny is determined by the average effects of the parent's alleles (Falconer, 1981, p 106). Thus, the breeding value of animal \( i \) for trait \( X \) in a multibreed population would be determined by the sum of the average effects of alleles all the breeds present in each of its parents:

\[
\text{u}_{iX} = a_{sX} + a_{dX}
\]  

[1]

where

- \( u_{iX} \) = random variable representing the breeding value of individual \( i \) for trait \( X \)
- \( a_{sX} \) = random variable representing the sum of the average effects of all alleles from all breeds affecting trait \( X \) coming from the gamete of the sire of animal \( i \), i.e.,

\[
a_{sX} = \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} \delta_{bk}a_{bk} \right)_{\text{sire}}, \text{ where } a_{bk} \text{ belongs to the sire of animal } i, \ k_b = \text{number of loci}
\]
in breed b, and $\delta_{bk}$ is a Kronecker delta, i.e., $\delta_{bk} = 0$ or 1; $\delta_{bk}$ will be zero ($2b/2$) times and one ($2b/2$) times, because a random sample of only $\frac{1}{2}$ of the male alleles from each breed is expected to be passed on to individual i.

$$a_{dX} = \text{random variable representing the sum of the average effects of all alleles affecting a trait, coming from the gamete of the dam of animal i, i.e.,}$$

$$a_{dX} = \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} \delta_{bk} a_{bk} \right)_{\text{dam}}, \text{ where } a_{bk} \text{ belongs to the dam of animal i.}$$

**Average genetic effects are defined as deviations from the average gene at each locus within each breed**: thus, the expected value of $u_{iX}$ is:

$$E[u_{iX}] = E[a_{sX} + a_{dX}]$$

$$= E[a_{sX}] + E[a_{dX}]$$

$$= E \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} \delta_{bk} a_{bk} \right)_{\text{sire}} + E \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} \delta_{bk} a_{bk} \right)_{\text{dam}}$$

$$= \left[ \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} E[\delta_{bk} a_{bk} | k, b] \right]_{\text{sire}} + \left[ \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} E[\delta_{bk} a_{bk} | k, b] \right]_{\text{dam}}$$

$$= 0 + 0$$

$$= 0$$

**The variance of $u_{iX}$ is:**

$$\text{var}(u_{iX}) = \text{var}(a_{sX} + a_{dX})$$

$$= \text{var}(a_{sX}) + \text{var}(a_{dX}) + 2 \text{cov}(a_{sX}, a_{dX})$$

**The covariance between the breeding values of animal i for traits X and Z is:**

$$\text{cov}(u_{iX}, u_{iZ}) = \text{cov}(a_{sX} + a_{dX}, a_{sZ} + a_{dZ})$$
\[ \text{cov}(a_sX, a_sZ) + \text{cov}(a_dX, a_dZ) + \text{cov}(a_sX, a_dZ) + \text{cov}(a_dX, a_dZ) \]

By conditioning on the breeding values of the sire \((u_sX)\) and the dam \((u_dX)\) of animal \(i\), \(\text{var}(u_iX)\) becomes:

\[
\text{var}(u_iX) = \text{var}(E[a_sX \mid u_sX]) + E[\text{var}(a_sX \mid u_sX)] \\
+ \text{var}(E(a_dX \mid u_dX)) + E[\text{var}(a_dX \mid u_dX)] \\
+ 2 \text{cov}(E[a_sX \mid u_sX], E[a_dX \mid u_dX]) \\
+ 2 E[\text{cov}(a_sX \mid u_sX, a_dX \mid u_dX)]
\]

But \(a_sX\) is the average effect of \(\frac{1}{2}\) of the alleles affecting the trait in the sire, i.e., \(a_sX = \frac{1}{2} u_sX\).

Thus,

\[
E[a_sX \mid u_sX] = E[\frac{1}{2} u_sX \mid u_sX] \\
= \frac{1}{2} u_sX
\]

Applying a similar argument to \(a_dX\) yields:

\[
E[a_dX \mid u_dX] = \frac{1}{2} u_dX
\]

Thus, for the sire of animal \(i\),

\[
\text{var}(E[a_sX \mid u_sX]) = \text{var}(\frac{1}{2} u_sX) \\
= \frac{1}{4} \text{var}(u_sX)
\]

\[
= \frac{1}{4} \left( \sigma_{AX}^2 a_s + \sum_{c=1}^{n_{cs}} \left( \frac{1}{2} a_{s,s,d,s} c_s \sigma_{AX}^2 c_s \right) \right)
\]

\[
= \frac{1}{4} \left( \sigma_{AX}^2 a_s + \sum_{c=1}^{n_{cs}} F_{cs} \sigma_{AX}^2 c_s \right)
\]

\[
(= \frac{1}{4} (\sigma_{AX}^2 + F_{cs} \sigma_{AX}^2) \text{ in a single breed population})
\]

where

\[
n_{cs} = \text{number of common ancestors for sire } s
\]
\[ (a_{sxd})_{cs} = \text{additive relationship between the sire and the dam of sire} \]
\[ \sigma^2_{AX} = \text{multibreed additive genetic variance for trait X of the sire} \]
\[ \sigma^2_{AX} = \text{multibreed additive genetic variance for trait X of the common ancestor of the sire and dam of sire s and, for the dam of animal i,} \]

Similarly, for the \textit{dam of animal i},

\[
\text{var}(E[a_{dX} | u_{dX}]) = \frac{1}{4} \left( \sigma^2_{AX} + \sum_{c=1}^{n_d} \frac{1}{2} a_{xd,dc} \sigma^2_{AX} \right)
\]
\[
= \frac{1}{4} \left( \sigma^2_{AX} + \sum_{c=1}^{n_d} F_{dc} \sigma^2_{AX} \right)
\]
\[
= \frac{1}{4} \left( \sigma^2_{AX} + F_d \sigma^2_{AX} \right)
\]

What is \(E[\text{var}(a_{dX} | u_{dX})] \)?

\[
E[\text{var}(a_{dX} | u_{dX})] = \text{var}(a_{dX}) - \text{var}(E[a_{dX} | u_{dX}])
\]

Here,

\[
\text{var}(a_{dX}) = \text{var} \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} \delta_{bk} a_{bk} \right)_{sire}
\]

Also, by definition,

\[
\text{var} \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} a_{bk} \right) = \sigma^2_{AX} = \text{multibreed additive genetic variance for trait X.}
\]

An expression for the multibreed additive genetic variance for trait X can be obtained by
conditioning on the breed of origin of alleles as follows:

\[ \sigma_{AX}^2 = \mathbb{E}[\text{var}(X \mid b)] + \text{var}(\mathbb{E}[X \mid b]) \]

\[ \sigma_{AX}^2 = \sum_{b=1}^{n_b} p_b^i \left( \sigma_{ax}^2 \right)_b + \sum_{b=1}^{n_b-1} \sum_{b'><b} (p_b^i p_{b'}^i + p_b^d p_{b'}^d) \left( \sigma_{ax}^2 \right)_{bb'} \]

where superscripts i, s and d correspond to animal, sire and dam, subscripts b and b' represent two breeds, and

\[ n_b = \text{number of breeds} \]

\[ p_b^x = \text{expected fraction of breed } b \text{ in animal } x, \ x = i, s, d \]

\[ (\sigma_{ax}^2)_b = \text{additive intrabreed variance of trait } X \text{ for breed } b \]

\[ (\sigma_{ax}^2)_{bb'} = \text{additive interbreed variance of trait } X \text{ for the pair of breeds } b \text{ and } b' \]

Thus, for the sire of animal i,

\[ \text{var}(a_{sx}) = \text{var} \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_s} \delta_{bk} a_{bk} \right)_{\text{sire}} \]

\[ = \frac{1}{2} (\sigma_{AX}^2)_s \]

and

\[ \mathbb{E}[\text{var}(a_{sx} \mid u_{sx})] = \frac{1}{4} \left( \sigma_{AX}^2 \right)_s - \frac{1}{4} \left( \sigma_{AX}^2 \right)_s - \sum_{c=1}^{n_s} \left( \frac{1}{2} a_{ss,ds} \right)_{cs} \left( \sigma_{AX}^2 \right)_{cs} \]

\[ = \frac{1}{4} \left( \sigma_{AX}^2 \right)_s - \sum_{c=1}^{n_s} \left( \frac{1}{2} a_{ss,ds} \right)_{cs} \left( \sigma_{AX}^2 \right)_{cs} \]

\[ = \frac{1}{4} \left( \sigma_{AX}^2 \right)_s - \sum_{c=1}^{n_s} F_{cs} \left( \sigma_{AX}^2 \right)_{cs} \]

\[ (= \frac{1}{4} (\sigma_X^2 - F_s \sigma_A^2) \text{ in a single breed population}) \]

Similarly, for the dam of animal i,
\[
\text{var}(a_{dX}) = \text{var} \left( \sum_{b=1}^{n_b} \sum_{k=1}^{2k_b} \delta_{bk} a_{bk} \right)_{\text{dam}} = \frac{1}{2} \left( \sigma_{AX}^2 \right)_d
\]

and

\[
\text{E}[\text{var}(a_{dX} | u_{dX})] = \frac{1}{4} \left( \sigma_{AX}^2 \right)_d - \frac{1}{4} \left( \left( \sigma_{AX}^2 \right)_d + \sum_{c=1}^{n_{cd}} \left( \frac{1}{2} a_{sd,cd} \right)_{cd} \left( \sigma_{AX}^2 \right)_{cd} \right)
\]

\[
= \frac{1}{4} \left( \sigma_{AX}^2 \right)_d - \frac{n_{cd}}{4} \left( \frac{1}{2} a_{sd,cd} \right)_{cd} \left( \sigma_{AX}^2 \right)_{cd}
\]

\[
= \frac{1}{4} \left( \sigma_{AX}^2 \right)_d - \frac{1}{4} \sum_{c=1}^{n_{cd}} F_{cd} \left( \sigma_{AX}^2 \right)_{cd}
\]

\[
(= \frac{1}{4} \left( \sigma_{AX}^2 - F_d \sigma_{AX}^2 \right) \text{ in a single breed population})
\]

The covariance terms of \( \text{var}(u_{dX}) \) are:

\[
2 \text{ cov} \left( \text{E}[a_{sX} | u_{sX}], \text{E}[a_{dX} | u_{dX}] \right) = 2 \text{ cov} \left( \frac{1}{2} u_{sX}, \frac{1}{2} u_{dX} \right)
\]

\[
= \frac{1}{2} \text{ cov} \left( u_{sX}, u_{dX} \right)
\]

\[
= \frac{1}{2} \left( \sum_{c=1}^{n_{c}} \left( a_{s,d} \right)_{cl} \left( \sigma_{AX}^2 \right)_{cl} \right)
\]

\[
= \sum_{c=1}^{n_{c}} \left( \frac{1}{2} a_{s,d} \right)_{cl} \left( \sigma_{AX}^2 \right)_{cl}
\]

\[
= \sum_{c=1}^{n_{c}} F_{cl} \left( \sigma_{AX}^2 \right)_{cl}
\]

\[
(= F_i \sigma_{AX}^2 \text{ in a single breed population})
\]

The value of \( 2 \text{ E}[\text{cov}(a_{sX} | u_{sX}, a_{dX} | u_{dX})] \) = 0 because the sire and the dam random samples of \( \frac{1}{2} \) of their respective set of alleles are taken independently of each other, i.e., there is no connection between the formation of sire gametes and dam gametes (biological fact). Thus,
Equivalent model for the breeding value of an animal for a single trait in a multibreed population

An equivalent model (same first and second moments; Henderson, 1985) to the single trait multibreed breeding value model,

\[ u_{iX} = a_sX + a_dX \]

\[ E[u_s] = 0 \]

\[ \text{var}(u_{iX}) = \sigma_{AX}^2 + \sum_{c=1}^{n_a} F_c \sigma_{AXc}^2 \]

is:

\[ u_s = \frac{1}{2} u_s + \frac{1}{2} u_d + \frac{1}{2} \varepsilon_s + \frac{1}{2} \varepsilon_d \]  

where

\[ u_{iX} = \text{breeding value of animal } i \text{ for trait } X \text{ (random),} \]

\[ u_{sX} = \text{breeding value of sire } s \text{ for trait } X \text{ (random)}, \]
\[ u_{dX} = \text{breeding value of dam } d \text{ for trait } X \text{ (random)}, \]
\[ \varepsilon_{sX} = \text{Mendelian sampling occurring during gametogenesis in sire } s \text{ for trait } X \text{ (random)}, \]
\[ \varepsilon_{dX} = \text{Mendelian sampling in dam } d \text{ for trait } X \text{ (random)}. \]

The Mendelian sampling terms \( \varepsilon_{sX} \) and \( \varepsilon_{dX} \) are independent of each other and independent from breeding values. All random variables have expected values equal to zero, i.e.,

\[ E[u_{iX}] = 0 \]

and

\[ \text{var}(u_{iX}) = \text{var}(\frac{1}{2} u_{sX} + \frac{1}{2} u_{dX}) + \text{var}(\frac{1}{2} \varepsilon_{sX}) + \text{var}(\frac{1}{2} \varepsilon_{dX}) \]

where

\[ \text{var}(\frac{1}{2} u_{sX} + \frac{1}{2} u_{dX}) = \text{var}(\frac{1}{2} u_{sX}) + \text{var}(\frac{1}{2} u_{dX}) + 2 \text{cov}(\frac{1}{2} u_{sX}, \frac{1}{2} u_{dX}) \]

\[ = \frac{1}{4} \left( \sigma_{AX}^2 + \sum_{c=1}^{n_s} F_{cs} \sigma_{AX}^2 \right) + \frac{1}{4} \left( \sigma_{AX}^2 + \sum_{c=1}^{n_d} F_{cd} \sigma_{AX}^2 \right) \]

\[ + \sum_{c=1}^{n_s} F_{cs} \left( \sigma_{AX}^2 \right)_{cs} \]

\[ = \frac{1}{4} \left( 1 + F_s \right) \sigma_A^2 + \frac{1}{4} \left( 1 + F_d \right) \sigma_A^2 + F_s \sigma_A^2 \text{ in a single breed population} \]

Because the sampling process during gamete formation (Mendelian sampling) in the male and female gametes is completely independent of each other, any loss of variation during this process would be due to (i) inbreeding in the male present in the male gamete, and (ii) inbreeding in the female present in the female gamete. Thus,

\[ \text{var}(\frac{1}{2} \varepsilon_{sX}) = \frac{1}{4} \left( \sigma_{AX}^2 \right)_{cs} - \frac{1}{4} \left( \sum_{c=1}^{n_s} F_{cs} \sigma_{AX}^2 \right) \]
\[
\text{var}(\frac{1}{2} \varepsilon_{dX}) = \frac{1}{4} \left( \sigma_{AX}^2 \right)_d - \frac{1}{4} \left( \sum_{c=1}^{n_{sd}} F_{cd} \left( \sigma_{AX}^2 \right)_{cd} \right)
\]

\[
\text{var}(\frac{1}{2} \varepsilon_{dX}) = \frac{1}{4} \left( \sigma_{AX}^2 \right)_d - \frac{1}{4} \left( \sum_{c=1}^{n_{sd}} F_{cd} \left( \sigma_{AX}^2 \right)_{cd} \right)
\]

(= \(\frac{1}{4} (1 - F_d) \sigma_a^2\) in a single breed population)

and

\[
\text{var}(u_{IX}) = \left( \sigma_{AX}^2 \right)_i + \sum_{c=1}^{n_{ci}} F_{ci} \left( \sigma_{AX}^2 \right)_{ci}
\]

(= \((1 + F_i) \sigma_a^2\) in a single breed population)

Remarks: \text{var}(\frac{1}{2} \varepsilon_{sX}) + \text{var}(\frac{1}{2} \varepsilon_{dX}) = \text{var}(\varphi_X)\) represents the variability that exists among gametes in the sire and in the dam. Thus, it is affected negatively by the level of inbreeding in the sire \((F_{sX})\) and dam \((F_{dX})\) and it is independent of the level of inbreeding of the individual \((F_{iX})\).

Derivation of general rules to compute the inverse of the multibreed additive covariance matrix directly

The multibreed additive genetic model can be generalized to include not only the case when both parents are identified, but also the cases when only the sire, only the dam or neither parent is known.

Unidentified parents are assumed to be non-inbred and unrelated among themselves and to all
other identified animals in the population, just like base animals.

**Base animals** are those that all other animals in the population descend from. They are assumed to be unrelated and non-inbred.

The **extended version of the multibreed additive genetic model** with animals ordered such that parents precede progeny (e.g., by birth date), in matrix notation, is:

\[ u_X = \frac{1}{2} P u_X + \varphi_X \]  

where

\[ u_X = \text{vector multibreed breeding values of animals for trait } X, \text{ where parents precede progeny}; \]

\[ P = \text{lower triangular matrix relating parents to progeny. A row of } P \text{ contains ones in the columns corresponding to the known parents and zeroes elsewhere. Thus, a row of } P \text{ contains:} \]

(i) two 1's if both parents are known,

(ii) one 1 if either the sire or the dam of an animal is known,

(iii) zeroes if both parents are unknown;

\[ \varphi_X = \text{vector of independent random variables representing:} \]

(i) Mendelian sampling in the sire and in the dam, if both parents of animal i are known, i.e.,

\[ \varphi_{iX} = \frac{1}{2} \varepsilon_{sX} + \frac{1}{2} \varepsilon_{dX} \]

(ii) Mendelian sampling in the sire and the dam plus:

(a) the breeding value of the dam, if only the sire of animal i is known, i.e.,

\[ \varphi_{iX} = \frac{1}{2} u_{dX} + \frac{1}{2} \varepsilon_{sX} + \frac{1}{2} \varepsilon_{dX} \]

(b) the breeding value of the sire, if only the dam animal i is known, i.e.,
(iii) the breeding value of animal $i$ if neither its sire nor its dam are known, i.e.,

$$ \varphi_{iX} = u_{iX} $$

From equation [3] we can see that:

$$ \varphi_X = (I - \frac{1}{2} P) u_X $$

$$ \Rightarrow u_X = (I - \frac{1}{2} P)^{-1} \varphi_X $$

$$ \Rightarrow E[u_X] = (I - \frac{1}{2} P)^{-1} E[\varphi_X] = 0 $$

$$ \Rightarrow \text{var}(u_X) = (I - \frac{1}{2} P)^{-1} \text{var}(\varphi_X) (I - \frac{1}{2} P')^{-1} $$

$$ \text{var}(u_X) = (I - \frac{1}{2} P)^{-1} D (I - \frac{1}{2} P')^{-1} $$

where

$$ D = \text{diag}\{\text{var}(\varphi_{iX})\} $$

$$ = \text{diag}\{d_{ii}\} $$

The $\text{var}(\varphi_{iX}) = d_{ii}$ are:

(i) $\text{var}\left(\frac{1}{2} \varepsilon_{iX} + \frac{1}{2} \varepsilon_{dX}\right) = \text{var}(u_{iX}) - \text{var}\left(\frac{1}{2} u_{iX} + \frac{1}{2} u_{dX}\right)$

$$ = \sigma_{AX}^2 + \sum_{c=1}^{n_s} F_{cA} \left(\sigma_{AX}^2\right)_{ci} - \frac{1}{4} \left(\sigma_{AX}^2\right)_h + \sum_{c=1}^{n_d} F_{cs} \left(\sigma_{AX}^2\right)_{cs} $$

$$ - \frac{1}{4} \left(\sigma_{AX}^2\right)_d + \sum_{c=1}^{n_d} F_{cd} \left(\sigma_{AX}^2\right)_{cd} - \sum_{c=1}^{n_s} F_{cs} \left(\sigma_{AX}^2\right)_{cs} $$

$$ = \sigma_{AX}^2 - \frac{1}{4} \left(\sigma_{AX}^2\right)_h - \frac{1}{4} \left(\sigma_{AX}^2\right)_d - \frac{1}{4} \sum_{c=1}^{n_d} F_{cd} \left(\sigma_{AX}^2\right)_{cd} $$

$$ - \frac{1}{4} \sum_{c=1}^{n_s} F_{cs} \left(\sigma_{AX}^2\right)_{cs} $$
if s and d are known

(ii) \[
\text{var} \left( \frac{1}{2} u_{dx} + \frac{1}{2} e_{sx} + \frac{1}{2} e_{dx} \right) = \text{var} \left( u_{ix} \right) - \text{var} \left( \frac{1}{2} u_{ax} \right)
\]

\[
= \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_s + \sum_{c=1}^{n_d} F_{cs} \left( \sigma_{AX}^2 \right)_{cs}
\]

\[
= \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_s - \frac{1}{4} \sum_{c=1}^{n_d} F_{cs} \left( \sigma_{AX}^2 \right)_{cs}
\]

if s is known only

(iii) \[
\text{var} \left( \frac{1}{2} u_{sx} + \frac{1}{2} e_{sx} + \frac{1}{2} e_{dx} \right) = \text{var} \left( u_{ix} \right) - \text{var} \left( \frac{1}{2} u_{dx} \right)
\]

\[
= \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_d + \sum_{c=1}^{n_d} F_{cd} \left( \sigma_{AX}^2 \right)_{cd}
\]

\[
= \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_d - \frac{1}{4} \sum_{c=1}^{n_d} F_{cd} \left( \sigma_{AX}^2 \right)_{cd}
\]

if d is known only

(iv) \[
\text{var} \left( \frac{1}{2} u_{sx} + \frac{1}{2} u_{dx} + \frac{1}{2} e_{sx} + \frac{1}{2} e_{dx} \right) = \text{var} \left( u_{ix} \right)
\]

\[
= \left( \sigma_{AX}^2 \right)_i
\]

if neither s nor d are known

But

\[
\text{var} \left( u_{ix} \right) = \left( I - \frac{1}{2} P \right)^{-1} D \left( I - \frac{1}{2} P^* \right)^{-1}
\]

\[
= G_{AX}
\]
\[ G_{AX}^{-1} = \left( I - \frac{1}{2} P' \right) D^{-1} \left( I - \frac{1}{2} P \right) \]

\[ G_{AX}^{-1} = D^{-1} - \frac{1}{2} D^{-1} P - \frac{1}{2} P' D^{-1} + \frac{1}{4} P' D^{-1} P \]

\[
\begin{bmatrix}
\frac{p_1'}{2} \\
\frac{p_2'}{2} \\
\vdots \\
\frac{p_n'}{2}
\end{bmatrix}
\]

Let \( P = \)

where \( p_i' \) is a vector with at most two 1’s and the rest zeroes.

Thus,

\[ -\frac{1}{2} D^{-1} P = \begin{bmatrix}
- \frac{1}{2} d_{i1} p_1' \\
\vdots \\
- \frac{1}{2} d_{nn} p_n'
\end{bmatrix} = \begin{bmatrix}
[sire] & [dam] \\
\vdots & \vdots \\
\cdots & - \frac{1}{2} d_{i1} & \cdots & - \frac{1}{2} d_{i1} & \cdots & [animal] \\
\vdots & \vdots
\end{bmatrix} \]

\[ -\frac{1}{2} P' D^{-1} = \begin{bmatrix}
- \frac{1}{2} d_{i1} p_1 \cdots - \frac{1}{2} d_{nn} p_n
\end{bmatrix} \]
Based on the pattern of contributions of the four matrices contributing to $GAXB^{-1}$, the following **rules to compute $GAXB^{-1}$ directly** can be inferred:

1. If both the sire (s) and the dam (d) of animal i are identified, add:
   
   $$d_{ii}^{-1} \quad \text{to} \quad i \times i$$
   $$-\frac{1}{2}d_{ii}^{-1} \quad \text{to} \quad i \times s, i \times d, s \times i, d \times i$$
   $$\frac{1}{4}d_{ii}^{-1} \quad \text{to} \quad s \times s, s \times d, d \times s, d \times d$$

   where
\[
d_{ii}^{-1} = \left[ \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_a + \frac{1}{2} \sum_{c=1}^{n_{ai}} F_{ci} \left( \sigma_{AX}^2 \right)_{ci} \right) - \frac{1}{4} \left( \sigma_{AX}^2 \right)_d + \frac{1}{2} \sum_{c=1}^{n_{di}} F_{cd} \left( \sigma_{AX}^2 \right)_{cd} \right]^{-1}
\]

(2) if only the sire (s) is known, add:

\[d_{ii}^{-1} \quad \text{to} \quad i \times i\]

\[-\frac{1}{2} d_{ii}^{-1} \quad \text{to} \quad i \times s, s \times i\]

\[\frac{1}{4} d_{ii}^{-1} \quad \text{to} \quad s \times s\]

where

\[d_{ii}^{-1} = \left[ \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_a + \frac{1}{2} \sum_{c=1}^{n_{ai}} F_{ci} \left( \sigma_{AX}^2 \right)_{ci} \right]^{-1}\]

(3) if only the dam (d) is known, add:

\[d_{ii}^{-1} \quad \text{to} \quad i \times i\]

\[-\frac{1}{2} d_{ii}^{-1} \quad \text{to} \quad i \times d, d \times i\]

\[\frac{1}{4} d_{ii}^{-1} \quad \text{to} \quad d \times d\]

where

\[d_{ii}^{-1} = \left[ \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_a + \frac{1}{2} \sum_{c=1}^{n_{ai}} F_{ci} \left( \sigma_{AX}^2 \right)_{ci} \right]^{-1}\]

(4) if neither s nor d are known, add:

\[d_{ii}^{-1} \quad \text{to} \quad i \times i\]

where

\[ d_{ii}^{-1} = \left( \sigma_{AX}^2 \right)_{ii} \]

These computational rules correspond to the multibreed version of Henderson’s rules.

In order to apply these rules we must know the \( d_{ii} \). If there is no inbreeding the \( d_{ii} \) can be easily computed using only the multibreed additive genetic covariances of the genetic groups of the animal, its sire, and its dam. But, if there is inbreeding, the computation of the \( d_{ii} \) requires knowledge of the inbreeding coefficients of each common ancestor of an animal and its corresponding multibreed variance for trait X. Because we are computing \( G_{AX}^{-1} \) without computing \( G_{AX} \) first, it is easier to compute the \( d_{ii} \) directly using a recursive procedure based on computing \( C \), where \( CC' = G_{AX} \). This approach will be used here.

**Rules to compute the \( d_{ii} \) in a non-inbred multibreed population**

If all animals in a multibreed population are non-inbred then:

1. if both the sire (s) and the dam (d) of animal i are identified, add:
   \[ d_{ii}^{-1} \text{ to } i \times i \]
   \[ -\frac{1}{2} d_{ii}^{-1} \text{ to } i \times s, i \times d, s \times i, d \times i \]
   \[ \frac{1}{4} d_{ii}^{-1} \text{ to } s \times s, s \times d, d \times s, d \times d \]

   where
   \[ d_{ii}^{-1} = \left( \sigma_{AX}^2 \right)_{ii} - \frac{1}{4} \left( \sigma_{AX}^2 \right)_{ii} - \frac{1}{4} \left( \sigma_{AX}^2 \right)_{ii} \]

2. if only the sire (s) is known, add:
   \[ d_{ii}^{-1} \text{ to } i \times i \]
$-\frac{1}{2} d_{ii}^{-1}$ to $i \times s, s \times i$

$\frac{1}{4} d_{ii}^{-1}$ to $s \times s$

where

$$d_{ii}^{-1} = \left[ \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_d \right]^{-1}$$

(3) if only the dam ($d$) is known, add:

$-\frac{1}{2} d_{ii}^{-1}$ to $i \times i$

$-\frac{1}{2} d_{ii}^{-1}$ to $i \times d, d \times i$

$\frac{1}{4} d_{ii}^{-1}$ to $d \times d$

where

$$d_{ii}^{-1} = \left[ \left( \sigma_{AX}^2 \right)_i - \frac{1}{4} \left( \sigma_{AX}^2 \right)_d \right]^{-1}$$

(4) if neither $s$ nor $d$ are known, add:

$d_{ii}^{-1}$ to $i \times i$

where

$$d_{ii}^{-1} = \left[ \left( \sigma_{AX}^2 \right)_i \right]^{-1}$$

The inverse of the $G_{AX}$ matrix is: $G_{AX}^{-1} = D^{-1} – \frac{1}{2} D^{-1} P \frac{1}{2} P' D^{-1} + \frac{1}{4} P' D^{-1} P$, where:

$$P = \begin{bmatrix}
0 & | & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & | & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & | & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & | & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & | & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & | & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{bmatrix},$$

$$D^{-1} = \begin{bmatrix}
(36)^{-1} & | & (9)^{-1} & | & (20.25)^{-1} & | & (13.5)^{-1} & | & (11.25)^{-1} & | & (15.625)^{-1} \\
\end{bmatrix},$$

thus
\[ G_{AX}^{-1} = \begin{bmatrix}
g^{11} & g^{12} & g^{13} & | & g^{14} & g^{15} & g^{16} \\
g^{22} & g^{23} & | & 0 & g^{25} & 0 \\
g^{33} & | & 0 & 0 & g^{36} \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\end{bmatrix} \]

where each \( g^{ij} \) term is computed using the recursive multibreed rules above, i.e.,

- \( g^{11} = (36)^{-1} + \frac{1}{4} (13.5)^{-1} + \frac{1}{4} (11.25)^{-1} + \frac{1}{4} (15.625)^{-1} \)
- \( g^{12} = \frac{1}{4} (11.25)^{-1} \)
- \( g^{13} = \frac{3}{4} (15.625)^{-1} \)
- \( g^{14} = -\frac{1}{2} (13.5)^{-1} \)
- \( g^{15} = -\frac{1}{2} (11.25)^{-1} \)
- \( g^{16} = -\frac{1}{2} (15.625)^{-1} \)
- \( g^{22} = (9)^{-1} + \frac{1}{4} (20.25)^{-1} + \frac{1}{4} (11.25)^{-1} \)
- \( g^{23} = -\frac{1}{2} (20.25)^{-1} \)
- \( g^{25} = -\frac{1}{2} (11.25)^{-1} \)
- \( g^{33} = (20.25)^{-1} + \frac{1}{4} (11.25)^{-1} \)
- \( g^{36} = -\frac{1}{2} (15.625)^{-1} \)
- \( g^{44} = (13.5)^{-1} \)
- \( g^{55} = (11.25)^{-1} \)
- \( g^{66} = (15.625)^{-1} \)
Multibreed Inbred Population

The multibreed additive genetic covariance of an animal with itself for trait X is:

\[ g_{ii} = \text{var}(u_{ix}) = \left( \sigma_{AX}^2 \right)_i + \sum_{c=1}^{n_{bx}} \left( \frac{1}{2} a_{sd} \right)_c \left( \sigma_{AX}^2 \right)_{ci} \]

or

\[ g_{ii} = \text{var}(u_{ix}) = \left( \sigma_{AX}^2 \right)_i + \sum_{c=1}^{n_{bx}} F_{ci} \left( \sigma_{AX}^2 \right)_{ci} \]

where

\[ (a_{sd})_{ci} = \text{additive genetic relationship between the sire (s) and the dam (d) of animal i through common ancestor ci} \]

\[ F_{ci} = \text{coefficient of inbreeding of animal i due to common ancestor ci} \]

\[ = \left( \frac{1}{2} a_{sd} \right)_i \]

In an inbred multibreed population the diagonal elements of the matrix D, i.e., the \( d_{ii} \), will depend on the coefficient of inbreeding of the parents of the animals included in the relationship matrix A. Thus, the \( d_{ii} \) cannot be computed based solely on knowledge of \( (\sigma_{AX}^2)_{bx} \), \( b = 1 \) to \( n_{bx} \), where \( n_{bx} \) = number of breed group combinations. We also need to know the coefficients of inbreeding of the parents thorough each one of their common ancestors weighted by the multibreed additive genetic covariances of their breed group. However, we do not need to compute the complete matrix \( G_{AX} \), only need the diagonal elements, because

\[ d_{ii} = \left( \sigma_{AX}^2 \right)_i - \frac{\delta_i}{4} \left( \left( \sigma_{AX}^2 \right)_s + \sum_{c=1}^{n_{bx}} F_{cs} \left( \sigma_{AX}^2 \right)_{cs} \right) - \frac{\delta_d}{4} \left( \left( \sigma_{AX}^2 \right)_d + \sum_{c=1}^{n_{bx}} F_{cd} \left( \sigma_{AX}^2 \right)_{cd} \right) \]

where
\[ \delta_i(d) = \begin{cases} 1 & \text{if } s(d) \text{ is known} \\ 0 & \text{otherwise} \end{cases} \]

Thus, what we need is an efficient method to compute the diagonal elements of \( G_{AX} \), i.e., the \( g_{ii} \).

This is accomplished by a recursive algorithm (Elzo, 1990), based on an algorithm developed by Quaas (1976) to compute the diagonals of the additive relationship matrix.

**Recursive method to compute the diagonals of the multibreed additive genetic covariance matrix \( G_{AX} \)**

The multibreed additive genetic covariance matrix \( G_{AX} \) is equal to:

\[
G_{AX} = \left( I - \frac{1}{2} P \right)^{-1} D \left( I - \frac{1}{2} P' \right)^{-1}
\]

**Claim:**

\[
\left( I - \frac{1}{2} P \right)^{-1} = I + \frac{1}{2} P + \left( \frac{1}{2} P \right)^2 + \left( \frac{1}{2} P \right)^3 + \ldots + \left( \frac{1}{2} P \right)^m
\]

where

\[
m = \text{maximum number of generations separating two individuals in } G_{AX}, \ m \leq n , \text{ where}
\]

\[
n = \text{order of matrix } G_{AX}
\]

\[
= \text{number of animals in the pedigree}
\]

**Proof (Quaas, 1986):** \( P \) is a lower triangular matrix with zeroes on and above the diagonal. Thus, \( P^{m+1} = 0 \) for \( m \leq n \).

Consider,

\[
T = I + \frac{1}{2} P + \left( \frac{1}{2} P \right)^2 + \ldots + \left( \frac{1}{2} P \right)^m
\]
and

\[
\left( \frac{1}{2} P \right)^T T = \frac{1}{2} P + \left( \frac{1}{2} P \right)^2 + \left( \frac{1}{2} P \right)^3 + \ldots + \left( \frac{1}{2} P \right)^m + \left( \frac{1}{2} P \right)^{m+1}
\]

Subtract the second term from the first term:

\[
T - \left( \frac{1}{2} P \right)^T T = I - \left( \frac{1}{2} P \right)^{m+1}
\]

But

\[
\left( \frac{1}{2} P \right)^{m+1} = 0
\]

Thus,

\[
\Rightarrow T \left( I - \frac{1}{2} P \right) = I
\]

\[
\Rightarrow T = \left( I - \frac{1}{2} P \right)^{-1}
\]

\[
\Rightarrow \left( I - \frac{1}{2} P \right)^{-1} = I + \frac{1}{2} P + \left( \frac{1}{2} P \right)^2 + \ldots + \left( \frac{1}{2} P \right)^m
\]

Remarks:

The rows of the matrices \( P, P^2, P^3, \ldots \), identify parents, grandparents, great-grandparents, ..., i.e.,

1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]
Let us look at the sums \( I + \sum_{c=1}^{j} \left( \frac{1}{2} P \right)^c \), \( j \leq 4 \), more closely.

\[
I + \frac{1}{2} P = \begin{bmatrix}
1.0 \\
0.5 & 1.0 \\
0.5 & 0.5 & 1.0 \\
0 & 0.5 & 0.5 & 1.0 \\
0 & 0 & 0.5 & 0.5 & 1.0
\end{bmatrix}
\]

\[
I + \sum_{c=1}^{2} \left( \frac{1}{2} P \right)^c = \begin{bmatrix}
1.0 \\
0.5 & 1.0 \\
0.75 & 0.5 & 1.0 \\
0.50 & 0.75 & 0.5 & 1.0 \\
0.25 & 0.50 & 0.75 & 0.5 & 1.0
\end{bmatrix}
\]
\[
\begin{align*}
I + \sum_{c=1}^{3} \left( \frac{1}{2} P \right)^c & = \\
\begin{bmatrix}
1.0 \\
0.5 & 1.0 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0.75 & 0.5 & 1.0 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0.625 & 0.75 & 0.5 & 1.0 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0.625 & 0.625 & 0.75 & 0.5 & 1.0 \\
0.625 & 0.625 & 0.75 & 0.5 & 0 & 1.0
\end{bmatrix}
\end{align*}
\]

**Generalizing:**

(1) The \(i^{th}\) row of \(T = \left( I - \frac{1}{2} P \right)^{-1}\) is equal to the sum of the \(i^{th}\) rows of \(I, \frac{1}{2} P, \left( \frac{1}{2} P \right)^2, \ldots, \left( \frac{1}{2} P \right)^m\), i.e., \(i^{th}\) row of \(T\) is equal to the sum of the \(i^{th}\) rows of \(I, \frac{1}{2} P, \left( \frac{1}{2} P \right)^2, \ldots, \left( \frac{1}{2} P \right)^m\).
However, the $i^{th}$ row of $T$ is also equal to the sum of the $i^{th}$ rows of $I$, $\left(\frac{1}{2}P\right)$, $\left(\frac{1}{2}P\right)^2$, ..., $\left(\frac{1}{2}P\right)^{m_i}$, where $m_i$ ($m_i \leq m$) is the number of generations separating animal $i$ from its oldest known ancestor.

(2) The parental rows of $I - \frac{1}{2}P$ are the same as the corresponding ones of

$I + \frac{1}{2}P + \left(\frac{1}{2}P\right)^2$, $I + \frac{1}{2}P + \left(\frac{1}{2}P\right)^2 + \left(\frac{1}{2}P\right)^3$, ..., and of

$I + \frac{1}{2}P + \left(\frac{1}{2}P\right)^2 + \left(\frac{1}{2}P\right)^3 + ... + \left(\frac{1}{2}P\right)^m \equiv T$.

Similarly, the parental rows of $I + \frac{1}{2}P + \left(\frac{1}{2}P\right)^2$ are the same as the corresponding ones of

$I + \frac{1}{2}P + \left(\frac{1}{2}P\right)^2 + \left(\frac{1}{2}P\right)^3$, ..., and $T$; etc. The reason for it is that the differences that exist between

$I + \sum_{c=1}^{i-1} \left(\frac{1}{2}P\right)^c$ and $I + \sum_{c=1}^{i} \left(\frac{1}{2}P\right)^c$

are related to accounting for the passage of alleles, from ancestors $c$ generations removed from each animal, to these same individuals. For instance, if $c = 3$, the difference between $I + \sum_{c=1}^{2} \left(\frac{1}{2}P\right)^c$

and $I + \sum_{c=1}^{3} \left(\frac{1}{2}P\right)^c$, are the elements of $\left(\frac{1}{2}P\right)^3$ which reflect the passage of alleles from great-grandparents to great-grandprogeny. Thus, rows of animals with unknown ancestors from the $c^{th}$ generation backwards remain unchanged, i.e., when the passage of alleles from all known
ancestors of an animal has been explained, its row will not change anymore. These fixed rows are called parental rows if these animals have progeny. In particular, notice that:

$$\begin{align*}
\text{the parental rows of } & \left\{ I + \sum_{c=1}^{m_i} \left( \frac{1}{2} P \right)^c \right\} = \text{the parental rows of } \\
\end{align*}$$

because the animals from the last generation have not become parents yet.

(3) The \(i\)\textsuperscript{th} row of \(T\) is a linear function of the rows of the parents of animals \(i\), i.e.,

$$\begin{align*}
i\text{th row of } \left\{ I + \sum_{c=1}^{m_i} \left( \frac{1}{2} P \right)^c \right\} = & \text{ i\textsuperscript{th} row of } \left\{ I + \frac{1}{2} P \left[ I - \sum_{c=1}^{m_i} \left( \frac{1}{2} P \right)^c \right] \right\} \\
= & \text{ 1 on diag } + \frac{1}{2} p_i' \left[ I + \sum_{c=1}^{m_i} \left( \frac{1}{2} P \right)^c \right]
\end{align*}$$

where

\(p_i' = \text{i\textsuperscript{th} row of } P\), it has at most two non-zero elements: a 1 on the column corresponding to the sire of animal \(i\) (\(s\)) and another 1 on the column of the dam of animal \(i\) (\(d\)), i.e.,

$$p_i' = [0 \ldots 010 \ldots 010 \ldots 0]$$

\(s \quad d\)

(4) Because \(T\) contains all the parental rows and the row for an animal is a linear function of the rows of its parents, a **recursive procedure to compute** \(T\) can be outlined as follows:

(i) Order animals such that parents precede progeny, numbering them from 1 (oldest) to \(n\) (youngest).

(ii) Compute the elements of \(T = \{t_{ij}\}\), one row or one column at a time, as follows:
(a) \( t_{ij} = \frac{1}{2} t_{n_{i},j} + \frac{1}{2} t_{d_{i},j} \) for \( j < i \) if \( s_i \) and \( d_i \) are known,

\[
= \frac{1}{2} t_{n_{i},j} \text{ for } j < i \\
= \frac{1}{2} t_{d_{i},j} \text{ for } j < i \\
= 0 \text{ for } j < i \\
= 0 \text{ for } j > i
\]

(b) \( t_{ii} = 1 \)

The matrix \( G_{AX} \), written in terms of \( T \), is:

\[
G_{AX} = T D \ T'
\]

Because \( D \) is diagonal and positive, \( D = D^{\frac{1}{2}} D^{\frac{1}{2}} \). Thus,

\[
G_{AX} = T D^{\frac{1}{2}} D^{\frac{1}{2}} T' \\
G_{AX} = CC'
\]

where

\[
C = T D^{\frac{1}{2}} \\
C = \text{Cholesky decomposition of } G_{AX}
\]

The elements of \( C \) can be computed recursively, using the procedure to compute \( T \), as follows:

(i) \( c_{ij} = t_{ij} d_{i j}^{\frac{1}{2}} \)

\[
= \frac{1}{2} \left( \delta_{s_{i}} t_{n_{i},j} + \delta_{d_{i}} t_{d_{i},j} \right) d_{i j}^{\frac{1}{2}} \text{ for } j < i
\]

where

\[
\delta_{s_{i}} (\delta_{d_{i}}) = 1 \text{ if } s_{i} (d_{i}) > 0
\]
\[ = 0 \text{ if } s_i(d_i) = 0 \]

(ii) \( c_{ii} = d_{ii}^{1/2} \)

\[ c_{ii}^2 = d_{ii} \]

\[ c_{ii}^2 = \left( \sigma_{AX}^2 \right)_i - \frac{\delta_{ii}}{4} \left( \sigma_{AX}^2 \right)_k + \sum_{c=1}^{n_{ii}} F_{c_i} \left( \sigma_{AX}^2 \right)_{c_i} - \frac{\delta_{ii}}{4} \left( \sigma_{AX}^2 \right)_d + \sum_{c=1}^{n_{ii}} F_{c_i} \left( \sigma_{AX}^2 \right)_{d_i} \]

\[ c_{ii}^2 = \left( \sigma_{AX}^2 \right)_i - \frac{\delta_{ii}}{4} g_{s,s} - \frac{\delta_{ii}}{4} g_{d,d} \]

But

\[ G_{AX} = CC' \]

\[ \Rightarrow g_{s,s} = \sum_{k=1}^{n_i} c_{s,k}^2 \]

\[ g_{d,d} = \sum_{k=1}^{d_i} c_{d,k}^2 \]

\[ \Rightarrow c_{ii}^2 = \left( \sigma_{AX}^2 \right)_i - \frac{\delta_{ii}}{4} \sum_{k=1}^{s_i} c_{s,k}^2 - \frac{\delta_{ii}}{4} \sum_{k=1}^{d_i} c_{d,k}^2 \]

\[ \Rightarrow \text{to compute the } d_{ii} = c_{ii}^2 \text{ we only need the squares of the diagonal elements of Cholesky matrix } C. \] Also, computations can proceed \textbf{one column at a time}. Consequently, the matrix C does \textbf{not} need to be stored to compute the \( g_{ii} \).

The computational procedure to obtain the \( g_{ii} \), proceeding one column at a time (Elzo, 1990), is as follows:

[1] Define:

\[ u = \text{ vector of sums of squares of the elements of a row of } C \]

\[ v = \text{ vector containing the diagonal elements of } C \text{ and work vector (used to store} \]
offdiagonal elements of $C$ temporarily)

[2] Order animals so that parents precede progeny and number them from 1 to $n$. Set the numbers of unknown parents to zero.

[3] For the $i^{th}$ round (i.e., the $i^{th}$ animal) compute:

(a) $v_i = c_{ii}$

$$= \left[ \left( \sigma_{AX}^2 \right) - \frac{1}{4} \left( u_i + u_d \right) \right]^{\frac{1}{2}}$$

if $s_i, d_i > 0$

$$= \left[ \left( \sigma_{AX}^2 \right) - \frac{1}{4} u_i \right]^{\frac{1}{2}}$$

if $s_i > 0, d_i = 0$

$$= \left[ \left( \sigma_{AX}^2 \right) - \frac{1}{4} u_d \right]^{\frac{1}{2}}$$

if $s_i = 0, d_i > 0$

$$= \left[ \left( \sigma_{AX}^2 \right) \right]^{\frac{1}{2}}$$

if $s_i = d_i = 0$

(b) $v_j = c_{ji}$ for $j = i + 1, ... , n$

$$= \frac{1}{2} v_{s_j} + \frac{1}{2} v_{d_j}$$

if $i \leq s_j, d_j$

$$= \frac{1}{2} v_{s_j}$$

if $d_j < i \leq s_j$

$$= \frac{1}{2} v_{d_j}$$

if $s_j < i \leq d_j$

$$= 0$$

if $s_j, d_j < i$

(c) $u_j = u_j + (v_j)^2$ for $j = i, ... , n$

(d) $d_{ii}^{-1} = (v_i)^{-2}$

[4] Compute and sum the contributions of the $i^{th}$ animal to $G_{AX}^{-1}$ using the multibreed recursive rules. If the matrix is too big to be kept in core, use a linked-list subroutine to sum and store
only the non-zero elements of $G_{AX}^{-1}$.

[6] If matrix $G_{AX}^{-1}$ is to be stored on disk or type, copy the non-zero elements accompanied by their row and column numbers.
